1. Start Convert2DOS by double-clicking the Convert2DOS icon.

2. In the Choose File dialog box, select the name of the MacDraw Pro file you want to convert.

3. In the Save Converted Files dialog box, select the location where you want the converted files saved. You can also change the name of the converted .MDP file, if necessary. (Convert2DOS automatically provides a name based on the name of the original MacDraw Pro file. For more information, see "File Naming Rules" later in this file.) If you change the name of the converted file, be sure to keep the .MDP extension as part of the name and to follow standard DOS file naming conventions (roots of file names can contain no more than eight characters and you cannot use invalid characters in the name, such as commas, spaces, and colons.)

4. After you select a location and a name for your converted files, click Save.Convert2DOS creates a converted .MDP file and a converted .RES file. You need both files in order to recreate the MacDraw Pro file in ClarisImpact for Windows. The name of the .RES file Convert2DOS creates is the same as that of the .MDP file except for the ".RES" extension. For example, if you enter the name MADRID.MDP in the Save Converted Files dialog box, Convert2DOS creates a file named MADRID.MDP and a file named MADRID.RES.

5. If you want to convert another MacDraw Pro file, select Convert from the File menu and return to step 2 of this procedure.

Disk Compatibility

If you are going to transfer the file between a Macintosh and a Windows machine or vice versa, you will need to overcome a floppy disk incompatibility hurdle. Macintosh and Windows machines format a 3.5 inch floppy disk differently, but there is software available that can read the opposing format. The Macintosh MUST be able to read and write to a 1.44 MB size floppy disk, which is also called a High Density floppy disk. A Macintosh disk drive that can read a 1.44 MB floppy disk is referred to as a FDHD floppy drive, a superdrive, or a high density floppy disk drive. The Windows machine must also have a 3.5 inch floppy disk drive.

a) The Macintosh can read and write files on and off of a Windows / DOS formatted floppy disk using file transfer software such as Apple File Exchange or PC Exchange, both made by Apple Computer, or third party products such as DOS Mounter. Apple File Exchange has shipped with Macintoshes for years and can be found on your set of original System 7 disks, in particular the Tidbits disk. PC Exchange came out in June of 1992 and is currently being bundled with Macintoshes such as the Performa models. For information on PC Exchange or Apple File Exchange, see your Macintosh User's Utilities Guide or visit the Apple Tech Info Library* on the World Wide Web.

*See PC Exchange/Apple File Exchange Info at the end of this document.

b) The Windows machine can read and write files on and off of a Macintosh formatted floppy disk drive using third party file transfer software such as Conversions Plus for Windows, made by Data Viz,Inc., or MAC-in-DOS.

Opening converted files in ClarisImpact for Windows

Important: Convert2DOS creates a pair of files for each original file you convert, one with the extension .MDP and one with the suffix .RES. You must keep each pair of files together in the same directory. If you change the name of an .MDP or .RES file, you must change the name of the other file in the pair so it matches. For example, if you change the name of the file MADRID.MDP to SPAIN.MDP, then you must also change the name of the file MADRID.RES to SPAIN.RES. Also, the new names you give to the files must end in ".MDP" and ".RES".

To open converted files in ClarisImpact for Windows:

1. Start ClarisImpact.

2. Choose Open from the File menu.

3. Find and select the appropriate .MDP file, and click OK. Your MacDraw Pro file opens in .CID format.

4. In ClarisImpact, save the file in .CID format. Once you save the file in .CID format, you can delete the corresponding .MDP and .RES files.

File naming rules

When Convert2DOS automatically assigns a name to converted files, it uses the first eight characters of the original MacDraw Pro file. If the name generated isn't compatible with Windows or is the same as a that of another file in the same directory, Convert2DOS changes the name. Here are some examples:

Original MacDraw Pro filename	**Translated filenames**
France:Paris	FRANCEPA.MDP, FRANCEPA.RES

LondonTownOne	LONDONTO.MDP, LONDONTO.MDP
LondonTownTwo	LONDONT1.MDP, LONDONT1.RES
LondonTownThree	LONDONT2.MDP, LONDONT2.RES

PC Exchange/Apple File Exchange Info

Additional information on PC Exchange and Apple File Exchange is available in the Apple Tech Info Library on the World Wide Web at **http://www.info.apple.com/til.html.**

Power Macintosh G3 (Blue and White): Internal Modem Technical Specifications

This article provides technical specifications for the Power Macintosh G3 (Blue and White) internal modem option.
This article has been archived and is no longer updated by Apple.

Hardware specifications

Operating voltage and current

+5 volts (V) at 435 milliamperes (mA); +12 V at 30 mA

Operating temperature

0° C to 40° C (32° F to 104° F)

Operating humidity

20 percent to 90 percent noncondensing

Operating altitude

0 to 3084 meters (0 to 10,000 feet)

Storage temperature

-40° C to +65° C (-40° F to +149° F)

Data communication standards

56,000 bits per second (bps) - K56flex V.90

33,600, 28,800, 26,400, 24,000, 21,600, 19,200, 16,800 bps - ITU V.34/V.FC

9600, 4800 bps - ITU V.32

2400 bps - ITU V.22 bis

2400 bps - Bell 212A

1200 bps - ITU V.22

1200/75 bps - ITU V.23

300 bps - ITU V.21

300 bps - Bell 103

Group 3 fax communication standards

14,400, 12,000 bps - ITU V.17

9600, 7200 bps - ITU V.29

4800 bps - ITU V.27 ter

2400 - ITU V.21

Miscellaneous specifications

AT command set

Extended Hayes AT command set

Error control

ITU V.42 (LAP-M), MNP Classes 2-4

Data compression

ITU V.42 bis

Data transmission and format

Full- or half-duplex operation, synchronous or asynchronous modes

Dialing capability

Tone or pulse dialing, automatic dialing

The International Telecommunications Union (ITU), one of the organizations working on forming international standards for communications, announced the ratification of the V.90 standard for 56K modems. Before the ratification of the V.90 standard, there were two proposed standards for 56K modems, x2 and k56flex. The optional internal 56K modem supports both the V.90 and k56flex standards.

System 7.5 Version 7.5.3: Available for Download

This article announces the availability of System 7.5, Version 7.5.3 for downloading. This software was released by Apple on January 30, 1999 and is available for download from the Apple Software Updates Web site at http://www.apple.com/swupdates.
This article has been archived and is no longer updated by Apple.
Requires:

System 7.5.3 requires an Apple Macintosh or PowerBook computer with at least 4MB of RAM. Note: newer Macintosh and PowerBook computers require versions of System software higher than version 7.5.3 in order to operate. See TIL article 8970 for information on which CPUs support System 7.5.3.

Description:

This is the North American English version of System 7.5 version 7.5.3, which includes the following system updates: System 7.5 Update 2.0 and System 7.5.3 Revision 2. For further information on System 7.5.3, please consult the Technical Information Library.

Instructions:

This software is available as 19 parts of a self-mounting Disk Copy image. Download all 18 parts to your hard drive and then double-click on the first part to mount the compressed disk image on your desktop.

Note: The self-mounting Disk Images require Mac OS version 7.0.1 or later. If you are using a version of Mac OS prior to this, you can download the System 7.5 Network Access floppy disk and boot your Macintosh from that to use this software.

Additional Information

The following Knowledge Base articles provide additional information on the installation and use of System 7.5 version 7.5.3:

Article 20060: "**Installing System 7.5, version 7.5.3 Read Me**"

Article 20242: "**Macintosh System 7.5, version 7.5.3: Description**"

Read/Write Optical Discs: Using for CD-ROM Emulation

I have an optical disc with data stored on it. I am considering putting the data on a CD-ROM, but am unsure of the performance I will get in a CD environment.

If I use a write lock on the optical disc, would this be a suitable emulation of a CD-ROM? If not, what do I need to do in order to emulate the performance of a CD-ROM with the optical disk?

This article has been archived and is no longer updated by Apple.

Using the optical disc in a write-lock mode is the best simulation of a CD-ROM that is available. However, note that some optical discs may have a slightly better performance than a CD-ROM.

Using the write-lock mode will help locate any possible write attempts prior to the pressing of the CD-ROM.

Most CD-ROM pressing facilities provide "one-off" CD-ROMs, which are actual CD-ROMs (but only one is created). This may be an additional expense, although the "one-off" provides an actual CD-ROM to see if all is correctly laid out. The "one-off" is created after using the data in the optical disc environment, prior to pressing the final CD-ROM.

Power Macintosh G3 (Blue and White): AppleWorks 5 Redraw Issue

When using AppleWorks 5 to create a shape in a word processing document using the circle tool, if you move the circle to a different location on the page the circle doesn't seem to redraw properly, leaving trails all over the document. If you disable the ATI Graphics Accelerator extension, the redraw behavior goes away.
This article has been archived and is no longer updated by Apple.
There is an issue with the ATI software installed on the Power Macintosh G3 (Blue & White) which can cause cosmetic redraw symptoms in AppleWorks, and possibly other applications. This issue is resolved in the ATI RAGE 128 Update 1.0, which is available on the Apple Software Updates web site.

This article can help you locate the software update mentioned here:

PowerBook 5300 System Software Update Removed

Apple has removed the software update for the PowerBook 5300 computer which included System Enabler 1.2.1. This article documents what to install in its place.

This article has been archived and is no longer updated by Apple.

In place of the PowerBook 5300 System Software Update with System Enabler 1.2.1, you can use System 7.5 Version 7.5.3 available from the Apple Software Updates Web site at http://www.apple.com/swupdates.

System 7.5.5 Update: Frequently Asked Questions (2 of 2)

This article contains part 2 of the answers to frequently asked questions (FAQ) about System 7.5.5 Update.

Part one is available at the following URL:

Article 20408: **System 7.5.5 Update: Frequently Asked Questions (1 of 2)**

Questions in this FAQ

1. When will System 7.5.5 Upda te be available in other languages beside U.S. English?
2. If I have any system running System 7.5.3, will I have all of the latest system software improvements after installing System 7.5.5 Update?
3. How can I tell if my system has been updated with System 7.5.5 Update?
4. How can I tell if a product which I purchased from Apple has the enhancements provided by System 7.5.5?
5. Along with the announcement of System 7.5.5 Update, it has been stated that this is the last system software release for the Macintosh Plus, SE, Classic, Portable, PowerBook 100, SE FDHD, SE/30, LC, II, IIx, and IIcx systems. Why are future versions of the Macintosh system software not supporting these systems?
6. If I have installed MODE32 on a Macintosh II, IIx, IIcx, or SE/30, does this mean my system will be supported by future releases of the Macintosh system software?
7. Are there any known problems with installing this update which I should be aware of?
8. What happened to System 7.5.4?
9. Where can I get System 7.5.5 Update?
10. What are the system requirements for System 7.5.5 Update?
11. Where can I get more information about the Mac OS?

This article has been archived and is no longer updated by Apple.

1) Question: When will System 7.5.5 Update be available in other languages beside U.S. English?

Answer: Apple expects localized versions of System 7.5.5 Update to be available in many countries within 90 days after the U.S. introduction. Please contact your local Apple support center for local availability.

2) Question: If I have any system running System 7.5.3, will I have all of the latest system software improvements after installing System 7.5.5 Update?

Answer: Yes.

3) Question: How can I tell if my system has been updated with System 7.5.5 Update?

Answer: If you have installed System 7.5.5 Update on to your system, there is a very easy way to verify that it has been installed. Choose "About This Macintosh" from the Apple menu. In the top right-hand side of this window will be the system software information. Your system has System 7.5.5 Update installed if it reads:

System Software 7.5.5

4) Question: How can I tell if a product which I purchased from Apple has the enhancements provided by System 7.5.5?

Answer: If you purchased a system from Apple which has the System 7.5..4 Update enhancements already included, the "About This Macintosh" window will read:

System Software 7.5.5

5) Question: Along with the announcement of System 7.5.5 Update, it has been stated that this is the last system software release for the Macintosh Plus, SE, Classic, Portable, PowerBook 100, SE FDHD, SE/30, LC, II, IIx, and IIcx systems. Why are future versions of the Macintosh system software not supporting these systems?

Answer: Future Mac OS releases will require a 68030, 63040, or PowerPC-based system which support 32-bit memory addressing, this includes all other Macintosh models. However, while future system software releases will not install on these older systems, Apple will still fully support

customers with these systems by providing telephone assistance.

6) Question: If I have installed MODE32 on a Macintosh II, IIx, IIcx, or SE/30, does this mean my system will be supported by future releases of the Macintosh system software?

Answer: No. System 7.5.5 Update is the last release which will support these hardware systems, regardless if MODE32 is installed.

7) Question: Are there any known problems with installing this update which I should be aware of?

Answer: Customers are encouraged to read the document which accompanies the update, titled "About System 7.5.5 Update". It has a "known problems section" which documents issues which Apple wants to make sure are brought to our customers' attention.

8) Question: What happened to System 7.5.4?

Answer: System 7.5.4 Update, which delivers System 7.5.4, was released by Apple Computer to a limited distribution, prior to an anticipated general release. Shortly after this limited distribution, a bug in the software was found which required a revision. This revision was named System 7.5.5 and replaces System 7.5.4. System 7.5.5 Update will install on computers which have System 7.5.4 installed.

Since System 7.5.4 was released to a limited audience, there needs to be a way to easily identify this release in the event one of our customers installed it and are having specific problems. In order to make identification of 7.5.4 easy, the version number was incremented to System 7.5.5.

9) Question: Where can I get System 7.5.5 Update?

Answer: System 7.5.5 Update is available electronically via:
* Apple ftp and World Wide Web sites
- **ftp://ftp.info.apple.com/**
- **http://www.apple.com/swupdates**

10) Question: What are the system requirements for System 7.5.5 Update?

Answer: In order to install the update, you must have System 7.5.3. System 7.5.5 Update cannot be installed on earlier versions of System 7.5.

11) Question: Where can I get more information about the Mac OS?

Answer: More information can be obtained about the Mac OS on the Internet at: **http://www.apple.com/macos**

Mac OS: Relationship of Desktop Icons to Storage Media

I noticed that after ejecting a Zip cartridge from my Macintosh, a few document icons also disappeared from my desktop. Why is that?
This article has been archived and is no longer updated by Apple.
This is normal behavior for the Macintosh Operating System. In this example, the documents that disappeared when you ejected the Zip disk are stored on the Zip disk itself, not on hard drive. When you ejected the disk, the icons went with it. They remain on the Zip disk and will reappear on the desktop when you re-insert the Zip disk.

This will hold true for any storage media, be it a floppy disk, CD-ROM, or hard drive.

If you wish to work with that document without the Zip disk inserted, copy the document to your computer's hard drive.

Power Macintosh G3 (Blue and White): Bus Error After Installing Displays Software 1.7

Installing the Apple Displays software version 1.7 included with the Apple Studio Displays can cause a bus error after restart. This article describes how to resolve the issue.

This article has been archived and is no longer updated by Apple.

Bus errors and/or freezing upon restart after installing the Apple Displays software version 1.7 are caused by corrupted PRAM. Resetting PRAM by holding down the Command-Option-P-R keys at restart until the computer chimes twice, appears to resolve the issue.

Apple Displays software version1.7.1 is available for download from the Apple Software Updates web site at **http://www.apple.com/swupdates**.

AppleShare IP: Idle User Disconnect Message Not Shown

If an AppleShare IP server has been configured to disconnect idle users after a certain period of time, and is configured to send a message to them when they are disconnected, some users may not receive this message when they are disconnected.

This article has been archived and is no longer updated by Apple.
Workstations using AppleShare client 3.7.4 and earlier receive the idle disconnect message. Workstations using AppleShare client 3.8 and later do not receive the message, but they are disconnected as scheduled. These clients receive other messages sent by the AppleShare IP administrator.

"File Server Uses Incompatible Version of the AFP Protocol" Error Resolution

When attempting to select a server in the Chooser, an error occurs saying "This file server uses an incompatible version of the AFP protocol. You cannot connect to it. Please contact the server's administrator." The server is using Personal File Sharing.
This article has been archived and is no longer updated by Apple.
This is the result of a network protocol communication error using AppleTalk Session Protocol.

When a file sharing client connects to a server, an AppleTalk Filing Protocol (AFP) connection is established. To initiate this connection, the client queries the server using AppleTalk Session Protocol (ASP).

Personal File Sharing servers and early version of AppleShare 3.0 had an issue, where they could send a zero length reply to a ASP Get Status. The client would interpret this as the server not having an AFP that it understands. (The versions of AFP that the server supports is part of the data returned in the ASP Get Status reply.) The result is that the client posts the specified error message.

This issue was fixed in 1993. If this issue occurs repeatedly, using recent modern Mac OS, the suspicion would be that the server software has become corrupted in memory somehow. Turning Personal File Sharing off and then back on had been reported to clear up this situation.

LaserWriter 8.6: Before You Install

This article comprises the Before You Install document for the LaserWriter 8.6 printer driver. This software was released by Apple on March 24, 1999 and is available for downloading from the Apple Software Updates Web site at http://www.apple.com/swupdates.

Description:

This software includes version 8.6 of the LaserWriter printer driver, which is included with Mac OS 8.5.

This article has been archived and is no longer updated by Apple.

Before You Install

This document contains important information about the LaserWriter version 8.6 software. You may want to print this document and keep it for future reference.

Installing the Printer Driver Software

Compatible Systems and System Software

You must use the Installer program to install the LaserWriter software. This version of the LaserWriter software is only supported on the Macintosh systems with the 68040 or Power PC family of Microprocessor. This software will only install on Mac System 7.6.1, Mac OS 8.1 and Mac OS 8.5 or later. If you are using a version of the Mac OS not listed, you must first upgrade your OS to use this software.

Installation notes: The LaserWriter 8.6 Read Me file will be installed into the Mac OS Read Me Files folder (located on your startup disk). Please refer to this file for additional tips on using your LaserWriter software.

If you are installing from floppy disks, before installing the printer software, restart your system with all extensions turned off. To do this, hold down the Shift key while you restart your computer. Hold the Shift key down until you see the message Extensions off, or until your normal desktop appears.

If you are installing from a CD-ROM, you may want to turn off or remove individual extensions which may conflict with the Installer. Do not turn off or remove the extension for the Apple CD-ROM.

The Installer does not remove versions of the LaserWriter printer driver earlier than version 8.0. If you no longer need these files, you may remove them from your System Folder.

The Installer does remove earlier versions of the LaserWriter 8 driver (for example, LaserWriter 8.0) and replaces the PPD files for Apple LaserWriter printers with the latest versions. You may want to archive your current LaserWriter 8 driver and PPDs before installing this software. To do this, drag the LaserWriter 8 and PrintingLib files from the Extensions folder to another folder. Drag your current PPDs from the Printer Descriptions folder to another folder.

LaserWriter Driver and Related Components

When you install this software, the Installer places the following files on your hard disk:

In the Extensions folder in the active System Folder:

- CFM-68K Runtime Enabler version 4.0 (System 7.6.1 w/68040 Microprocessors)
- Desktop Printer Extension version 2.1 (System 7.6.1 Only)
- Desktop Printer Menu version 2.1 (System 7.6.1 and Mac OS 8.1) or 2.2.1 (Mac OS 8.5 and Later)
- Desktop Printer Monitor version 2.1 (System 7.6.1 and Mac OS 8.1) or 2.2.1 (Mac OS 8.5 and Later)
- Desktop Printer Spooler version 2.1 (System 7.6.1 and Mac OS 8.1) or 2.2.1 (Mac OS 8.5 and Later)
- LaserWriter 8 version 8.6
- PrintingLib version 8.6
- PrintMonitor version 7.1.2f1
- NuQuickTimeLib.slb version 2.0.1 (System 7.6.1 w/68040 Microprocessors)
- NuThreadsLib.slb version 2.1.1 (System 7.6.1 w/68040 Microprocessors)
- ObjectSupportLib version 1.2 (System 7.6.1)
- IrDALib version 1.1.5 (IrDA Capable PowerBooks Only)*
- IrDA Tool version 1.1.5 (IrDA Capable PowerBooks Only)*
- IrDALanScannerPPC version 1.1.5 (IrDA Capable PowerBooks Only)*

In the Control Panels folder in the active System Folder:

- Infrared version 1.1.5 (IrDA CapiableSystems Only)*

In the Control Strip Modules folder in the active System Folder:

- Print Selector version 2.1 (System 7.6.1 and Mac OS 8.1) or 2.2.1 (Mac OS 8.5 and Later)

In the Scripting Additions folder in the active System Folder:

- Desktop Printer Manager version 1.0 (Mac OS 8.5 or Later)

In the Printer Descriptions folder in the Extensions folder in the active System Folder:

- PostScript Printer Description (PPD) files for Apple LaserWriter printers (Various versions)

In the Apple LaserWriter Software Folder:

- Desktop Printer Utility version 1.1

In the Mac OS Read Me Files Folder in the Start-up Disk:

- LaserWriter 8.6 Read Me version 1.1

* IrDA Capable PowerBooks are: Apple PowerBook 2400, Apple PowerBook 3400, Apple PowerBook G3, and all Apple PowerBook G3 Series PowerBooks.

Note: If the Installer is unable to remove old files from your hard disk, it will terminate the installation procedure. If this happens, remove old copies of the files listed above from their respective folders and try the install again.

Other Issues and Tips

Desktop Printer Icons Appear Inactive - When switching Mac OS systems, Desktop Printers may appear inactive when they should be active. This can be resolved by rebuilding the desktop printer database. The desktop printer database can be rebuilt by restarting your Macintosh with the Command and Option keys pressed down until the desktop has been rebuilt.

After Install, If No Default Desktop Printer Is Selected - After the software installation is complete and your system has restarted, check that you have a default desktop printer selected. The default desktop printer has a bold line surrounding it. If you do not have a default desktop printer, highlight the Desktop Printer icon that you want to use as the default printer and press the Command and L keys at the same time, or from the Printing menu, select "Set Default Printer".

Printer Descriptions Folder Alias - If the Printer Descriptions folder has been moved to somewhere other than the Extensions folder, and an alias is in its place, be sure to remove the Printer Descriptions alias before running the Installer.

Removing Unneeded PostScript Printer Descriptions - This software installs over thirty LaserWriter PostScript Printer Descriptions (PPD). To remove unwanted PPDs, open this folder on your system after you are finished installing the software: System Folder: Extensions: Printer Descriptions. You will see displayed all the currently existing PPDs. PPDs are listed by printer model name. If you see PPDs that you will not be using, drag them to the trash.

Sherlock: What Search Operators Are Supported?

Does Sherlock support any specific search operators?

This article has been archived and is no longer updated by Apple.
Because Sherlock has the capability to search across multiple search engines simultaneously, no specific search operators are supported. Sherlock will pass the exact words you type in to all selected search engines and they will act upon the search string depending upon their own criteria.

A search operator is used to help narrow down a search. The most common operators are: and, or, not, adjacent.

Data Modem 2400: Configuring for Credit Card Dialing

I have a Macintosh Portable which is now equipped with an Apple Macintosh Portable Modem. When used to dial local numbers or when dialing direct, it works just like a Hayes modem is supposed to.

In my use of the Portable however, I often dial long distance numbers. My technique for doing this is to dial with a 0 (instead of a 1) and then dial my credit card number. On a normal Hayes modem, this is done as follows:

ATDT013012869000;

Notice the semicolon at the end of the dial string, which tells the modem to return to command mode when done with the phone number.

As the call is completed, AT&T will come around and ask for a credit card number. Since the modem is still in command mode, I give the following command:

ATDT1234567890

This command tells the modem to send my credit card number. After this, the call is typically completed and I can do my stuff.

The trouble with the Macintosh Portable modem is that when it is given the second command string, it hangs up the phone before doing the credit card number. This is not good. I need a solution.

This article has been archived and is no longer updated by Apple.
Your problem is caused by a feature of the Macintosh Portable Data Modem 2400 and its use of the dial command. The feature in question is dial tone sensing -- waiting for a dial tone before actually dialing the requested number. It is a common feature of many, but not all, Hayes and Hayes-compatible modems and actually originated with another modem manufacturer.

When you issue the first dial command, the modem goes off-hook, waits for a dial tone, and then dials the number. After the second dial command, the modem (which is already off-hook) again waits for a dial tone. Since there is no dial tone present at this stage of a credit card call, the modem waits 2 seconds as specified by modem register S6 and goes on-hook without dialing the credit card number. It should also alert the user with a NO DIALTONE message.

There are a couple of ways to get around the problem. The first and probably most acceptable way is to use additional dial command options designed just for this kind of situation.

The W modifier can be put in the middle of a dial string to cause the modem to wait for a "secondary" dial tone such as that generated by AT&T "dial 0 first" calls.

ATTD 0 123 456-7890 W 12345678901234

The above command dials the destination number, and then pauses at the W for a secondary dial tone. When the secondary dial tone is detected, the rest of the number is dialed -- in this case, the credit card number. The number of seconds the modem will wait for the secondary dial tone is controlled by the value of modem register S7.

Some long distance services do not generate this secondary dial tone, and in these cases a different modifier must be used. The @ symbol causes the modem to wait for a 5-second silence before continuing, and is one alternative.

ATDT 0 123 456-7890 @ 12345678901234

This dials the destination number and then waits for a 5-second silence before dialing the credit card number. If the 5-second silence isn't detected within the number of seconds in modem register S7, the modem will go on-hook and display the message NO ANSWER.

Another useful modifier is the comma character. It will generate 2-second pauses (controlled by modem register S8) while dialing. Two in a row would cause a 4-second pause.

ATDT 0 123 456-7890 ,, 12345678901234

This dials the destination part of the number and pauses 4 seconds before dialing the credit card number.

The 5-second delay usually works, but is often excessive. Combinations of commas can generate just the right amount of delay, depending on the long distance carrier being used.

One last item to note is that the dial tone sensing is only active when result code set 2 or 4 is used. This is controlled by the ATXn command, where n is a value from 0 to 4 inclusive. If 0, 1, or 3 is used, your original method of dialing would work.

Power Macintosh G3 (Blue and White): Which Zip Drive to Use For Upgrade

Upgrading your Power Macintosh G3 does not require a specific Zip drive from Apple, so you can obtain an ATAPI Zip drive from your favorite vendor.

This article has been archived and is no longer updated by Apple.
Apple has an upgrade kit available from the Apple Store online at http://www.store.apple.com, or through your local Authorized Apple Reseller. The part number is M7551LL/A.

If your computer did not come with a Zip bezel, you may obtain one from your Apple Authorized Service Provider or a third party company. The Apple part number is 076-0762.

USB Enabled Macintosh: ADB AppleVision Display Support

Using an older AppleVision or Apple Studio display that required ADB for certain features is not directly supported on newer Power Macintosh and PowerBook computers that lack an ADB port. This article provides further information on using older ADB based displays on newer computers such as the PowerBook (FireWire) or the Power Mac G4.
This article has been archived and is no longer updated by Apple.
While not explicitly supported, displays that require ADB can function provided the appropriate video card or port is available. However, certain features that rely on ADB, such as ColorSync and on-screen geometry adjustments, do not.

There are ADB to USB adapters available that may return the ColorSync and on-screen geometry adjustment functionality. To locate available adapters, go to the Apple USB products page at **http://guide.apple.com**. From there you can search for USB adapters.

PowerBook G3 Series (Bronze Keyboard): Battery and Expansion Bay Compatibility

This article describes the battery and expansion bays used in the PowerBook G3 Series (Bronze Keyboard).
This article has been archived and is no longer updated by Apple.
The PowerBook G3 Series with Bronze keyboard has two battery bays similar to earlier PowerBook G3 Series computers. However, the left bay works with a battery only, while the right bay works with a battery or expansion bay device like a CD-ROM drive, or Zip drive.

The battery and expansion bay devices from the earlier PowerBook G3 Series do not work with the PowerBook G3 Series (Bronze keyboard) because they are too tall. The proper battery model number for the PowerBook G3 Series (Bronze keyboard) is M7385G/A.

Apple ships the PowerBook G3 Series (Bronze keyboard) with a expansion bay blank (weight saving module) which takes the place of either a battery or expansion bay device. This module protects the expansion bay from foreign material when an expansion bay device is not installed.

Apple does not provide a floppy drive module for the expansion bay.

Published Date: Feb 18, 2012

ALERT: "Steroid" Trojan Horse

This article discusses the effects of a Trojan Horse called "Steroid", and some suggestions on repairing the losses it can cause.

This article has been archived and is no longer updated by Apple.
The Trojan Horse called "Steroid" is an INIT that claims to speed up QuickDraw on Macintosh computers with 9-inch screens. The INIT contains code that checks for the date being greater than June 6, 1990. If it is, it erases all mounted drives.

We have performed some tests on a Macintosh SE. Having Comm Toolbox installed seemed to interfere with the INIT and kept the erase from happening: the Macintosh SE simply crashed instead.

We then installed the INIT on a floppy disk and booted the Macintosh SE. The floppy and hard disk were promptly erased. NOTE: We had set the date to one LATER than June 6, 1990.

So far, we know that the code does the following operations at restart:

Operations at Restart

DATE & TIME CHECK (Loop)
SYSENVIRONS CHECK
GETS VOLUME INFORMATION (probably checking for HFS)
GETS SOME ADDRESSES (Toolbox traps)
DOES SOME HFS DISPATCH OPERATIONS
VOLUME IS REINITIALIZED to "Untitled"

Information

TYPE: INIT
CREATOR: qdac
CODE SIZE: 1080
DATA SIZE: 267
ID: 148
Name: QuickDraw Accelerator
File Name: " Steroid" (first two characters are ASCII 1)

What To Do

If your disk becomes erased, you can use SUM II Disk Clinic to recover the deleted files. We have tried this and it seems to work.

PowerBook (Bronze keyboard and FireWire): No Traditional Serial Ports

Does the PowerBook G3 Series (Bronze keyboard) or PowerBook (FireWire) support ADB or traditional serial devices?
This article has been archived and is no longer updated by Apple.
No, there are no ADB or serial ports on the computer. Instead, the computers have two USB ports for connecting keyboards, mice, or other USB peripherals. The PowerBook (FireWire) adds two 400 Mbps FireWire ports for connecting FireWire devices such as DV cameras or hard drives.

If you have need to connect serial or ADB devices, there are a number of third party adapters for using serial devices on the USB port. Refer to the Apple USB homepage for additional information on USB adapters and products at **http://www.apple.com/usb**.

PowerBook G3 Series (Bronze keyboard): How to Determine if DVD Decoder is Present

This article tells how to use Apple System Profiler to determine whether the DVD decoder is present on the logic board of your PowerBook G3 Series (bronze keyboard) computer.

This article has been archived and is no longer updated by Apple.
The most reliable way to determine if the DVD decoder is present on the logic board is by using the Apple System Profiler. Under the Hardware Overview tab the following appears if the DVD decoder is installed:

Figure 1, Apple System Profiler Hardware Overview tab

You can also look on the underside of the PowerBook; the product ID label has DVD on it if the decoder is installed.

Note: If the PowerBook G3 Series (Bronze keyboard) did not come pre-configured for DVD decoding, there is no upgrade available from Apple to provide that capability.

PowerBook (Bronze keyboard or FireWire): Drive Height Specification

This article provides the drive height specification for the PowerBook G3 Series (bronze keyboard) and PowerBook (FireWire) computers.

This article has been archived and is no longer updated by Apple.
The hard disk drive must be no taller than 12.7mm or 0.5 inch for either PowerBook.

Published Date: Feb 18, 2012

AppleShare 2.0 & Older Versions: Recommended Memory Use (8/95)

Extra memory in an AppleShare file server is automatically given to RAM cache. But because of the algorithms used by Macintosh RAM cache, some have told me that a 2MB server is actually FASTER than a 5MB server.

Is this the case? Are there any recommendations for memory size for:

File Server Only
File Server and Print Server
File Server with Internet Router
File Server and Print Server with Internet Router

If I'm using a Macintosh II as a file server with 2MB of memory (and under the maximum of 50 users) what's the benefit of another 3MB of memory for the file server? I know that the RAM cache will increase (it's at 1024K already, though with 2MB) and that will (theoretically) speed things up, but I've switched back and forth, and don't see much of a difference.

This article has been archived and is no longer updated by Apple.
AppleShare File Server runs in about 1MB of RAM. Any memory beyond this 1MB is given to RAM cache, to cache directory structures, user data files, and so on. Thus, in a 2MB machine, 1MB will be used for caching. As cache size increases, more of the disk directory can be maintained in memory. This results in fewer disk accesses and faster response. Users' data files are also maintained in cache when there is room. This is effective with multi-user applications when several users access the same data file.

In general, 1MB of cache memory is quite adequate. Any more memory beyond this will not buy you much -- and can degrade performance, as you were told. This is why you did not see the difference between a 3MB and a 5MB machine.

For a File Server only, 1MB to 2MB memory is recommended. A 1MB Macintosh server can support 25 concurrent users. A 2MB Macintosh II can support 50 concurrent users.

To run the AppleShare File Server with the Internet Router or the AppleShare Print Server, or both, the minimum memory requirement is 2MB. You should run about 4MB to achieve better performance.

For more information about memory requirement when running the Internet Router with the File Server and the AppleShare Print Server, search the Tech Info Library using keywords "Internet Router" and "memory".

PowerBook G3 Series (Bronze keyboard): Modem Compatibility

The modem in the original PowerBook G3 Series does not work in the PowerBook G3 Series (Bronze keyboard).

This article has been archived and is no longer updated by Apple.
The new PowerBook G3 Series uses a new modem design that places the modem and RJ-11 jack on two separate boards. The modem ports are also in different locations on the two computers.

On the PowerBook G3 Series the modem port is on the left side next to the PC card slot. On the PowerBook G3 Series (Bronze keyboard), the modem port is at the rear of the computer.

PowerBook G3 Series (Bronze keyboard): Occasional Lack of Audible Feedback from Volume Buttons

I have noticed that on my PowerBook G3 Series (Bronze keyboard) sometimes the volume buttons don't make an audible beep unless I increase the volume to the maximum. Why is this?

This article has been archived and is no longer updated by Apple.

In certain circumstances the system software may think that a CD is playing when in fact it's not. For example this can happen after a CD has played all the way to the end and stopped on its own. In this condition, the volume buttons will not make beep sounds when pressed unless the volume is increased to the maximum. Visual feedback is still provided, however.

Published Date: Feb 18, 2012

PowerBook G3 Series (Bronze keyboard): Difference Between PowerBook SCSI Control Panels

I did a Universal Install of Mac OS 8.6 and I have two similar control panels. One is called PowerBook SCSI Disk Mode and the other is called PowerBook SCSI Setup. What's the difference?
This article has been archived and is no longer updated by Apple.
Although the control panels have similar names, they have slightly different functions and should not both be used on the same model of PowerBook.

The PowerBook SCSI Disk Mode control panel should be used with any PowerBook model available before the PowerBook G3 Series (Bronze keyboard). It allows you to set the SCSI Disk Mode address on the PowerBook when you connect the PowerBook to another Macintosh as a SCSI disk drive.

The PowerBook SCSI Setup control panel should be used on the PowerBook G3 Series (Bronze keyboard). It allows for the same functionality but in addition it also offers the option to scan for and mount SCSI devices when coming out of sleep.

PowerBook G3 Series (Bronze keyboard): NetBooting with Mac OS 8.5.1 Not Supported

My PowerBook G3 Series (Bronze keybard) came with Mac OS 8.6 pre-installed but I'm able to NetBoot with the default Mac OS 8.5.1 NetBoot HD.img.
This article has been archived and is no longer updated by Apple.
The NetBoot HD.img must be updated to Mac OS 8.6 by the NetBoot Server administrator in order to properly support NetBooting PowerBook G3 Series (Bronze keyboard) computers.

The NetBoot Server Administrator should additionally install the Battery Module Control Strip module and the ATI Resource Manager extension contained in the Important Extra System Software folder on the PowerBook Install CD, the contents of which are shown below.

The third component, the Modem Sound TuneUp extension, should only be installed on the image when PowerBook G3 Series computers are intended to be the only NetBoot clients. The Modem Sound TuneUp extension should not otherwise be installed as it is not appropriate for use with the modems in iMacs and Power Macintosh G3s (Blue & White).

Figure 1, Modem Sound TuneUp icon (bottom right)

While Mac OS 8.5.1 may boot a PowerBook G3 Series (Bronze keyboard), it does not represent a supported configuration. Mac OS 8.6 and its corresponding Mac OS ROM file were developed in part to support certain hardware features of the PowerBook G3 Series and, as such, is the minimum supported version of the Mac OS on this computer.

PowerBook G3 Series (Bronze keyboard): Sleep Indicator LED Glows Steadily at Startup

When waking a PowerBook G3 Series (Bronze keyboard) from sleep, the sleep indicator light glows steadily for a short time before the computer wakes up.

This article has been archived and is no longer updated by Apple.
This is normal behavior for the PowerBook. While the LED is on the computer is reloading the power manager code. This provides the information to the computer relative to power management and battery charging. It should not happen every time you wake the computer from sleep but it happens occasionally and is not considered a fault.

MacDFT: IBM Environment Printing Support

DCA MacIrma supports printing with the IBM standard $IND file transfer mechanism.

MacDFT doesn't seem to support that function. Why?

This article has been archived and is no longer updated by Apple.
We are not clear how you are using file transfer service IND$ for printing. DCA MacIrma supports printing via LU Type 3 devices to IRMAPrint attached printers. Tri-Data Systems, Inc.'s Netway supports printing via LU Type 3 device to LAN-based LaserWriters.

In the IBM environment, Local copy means sending a snapshot of your screen to the control unit, which prints it on a 3287 printer. Host Local copy printing means printing a host file on a 3287 printer connected to the terminal. MacDFT version 1.1 does not support host or terminal local copy. However, you can create a screen image that you can save to disk or print from the Macintosh II computer during a MacDFT session.

You can print documents and files produced during your MacDFT session on an Apple printer that is connected to your Macintosh. You can print host-resident documents to an IBM printer that is connected to your control unit or host. Use the print commands that are supported in your IBM environment.

PowerBook (Bronze keyboard and FireWire): No Ethernet Cable in Accessory Kit

My computer did not come with an Ethernet cable in the accessory kit. Was it supposed to have one?
This article has been archived and is no longer updated by Apple.
No, an Ethernet cable is not included in the PowerBook G3 Series (Bronze keyboard) or PowerBook (FireWire) accessory kit..

If you are going to connect your computer to an Ethernet network you will need to purchase the appropriate cable. If you are planning to connect to a 100 base Ethernet network, is important that the cable be rated as a Category 5 (Cat 5) cable .

PowerBook G3 Series (Bronze keyboard): About Important Extra System Software Folder

My PowerBook G3 Series (Bronze keyboard) CD has an Important Extra System Software Folder. What is it for?
This article has been archived and is no longer updated by Apple.
About the contents of the Important Extra System Software Folder.

This folder contains:

Read Me entitled "Important Extra System Software".

ATI Resource Manager

Battery Monitor

Modem Sound TuneUp

Mac OS ROM

Your computer came with all necessary system software already installed. However, if you use the Mac OS Install program on the PowerBook G3 Series CD to reinstall your system software you will need to install the items in the Important Extra System Software folder separately.

To install the extra system software:

1. After reinstalling the Mac OS, drag and drop the items from this folder on top of a closed system folder on your hard disk.
2. Click OK when asked to put the items in their proper location.
3. Restart your computer.

PowerBook G3 Series (Bronze keyboard): Important Information About the PowerBook G3 Series CD

This article comprises the Important Information About the PowerBook G3 Series CD Read Me.
This article has been archived and is no longer updated by Apple.

Important Information About the PowerBook G3 Series CD

Some of the items on your PowerBook G3 Series CD have been preinstalled on your computer's hard disk. You can find out about each of these programs or documents by opening its folder and reading the Read Me file.

Backing Up Software

The PowerBook G3 Series CD contains a copy of all the software that was originally installed on your hard disk. You can restore the complete set of software to the hard disk (or make a copy on another disk) using the Apple Software Restore program on the CD. See the file Restoring PowerBook Software for instructions.

You cannot use the restore program to make floppy disks.

Starting Up from the CD

If you are not able to start up the computer from the hard disk, you can use the CD as your startup disk. To start up from the CD, hold down the C key after you press the Power key.

The PowerBook G3 Series CD contains a minimal System Folder. Consequently, you cannot run the programs included on the CD until you restart the computer with another startup disk. Also, when the CD is the startup disk, you cannot install some programs from the CD to your hard disk.

Macintosh: Controlling Multimedia Peripheral Devices

1) Is there any product available that allows peripherals like the video cassette recorder, LaserDisc player, large screen projector, slide projector, sound system, lighting system, and so on, to be controlled from the Macintosh? How about a product that can control the VCR and get it to go to certain frames on the video cassette (just like the way the Macintosh can control the LaserDisc player).

2) Are there any products around that can record the Macintosh screen display into PAL video format?

This article has been archived and is no longer updated by Apple.

1) We do not know of one commercial product that can control all of the listed peripherals. However, there are products for controlling most of the individual peripherals separately.

- VCRs, camcorders and still video cameras with Control-L (Sony's video control standard) can be controlled via VidClip XCMDs for HyperCard, which are available from APDA. At this point, it appears that only Sony equipment uses the Control-L protocol. Sony does have 8mm VCRs, VHS VCRs, and still video cameras/players that support the Control-L protocol.

- There are XCMDs for HyperCard that can control many of the laser disc players. These XCMDs are available from Voyager.

- Sound systems and lighting systems can be controlled via MIDI. Audio mixing boards, audio equalizers, audio delay and reverb devices, and lighting control boards exist that have MIDI connections built in. A visit to a professional musicians' store should provide an array of possibilities for MIDI-controlled sound and lighting systems.

- Slide projectors usually have a cable-attached button controller for advancing/reversing slides. These button controllers can be replaced with a MIDI-controlled device from Peavey Electronics. Peavey is a music instrument manufacturer that recently produced a line of MIDI-controlled devices for controlling various items used in live performance music. One of these devices can replace the slide projector's remote control. Again, a professional musicians' store that carries Peavey products can supply this device.

- VidClip provides the control access to go to certain locations on tape. However, going to a specific frame on tape is not as easy as on disc. It is possible to get within about 5 frames with the typical Control-L VCR. Since recording single frames on low- to moderate-cost VCRs is not possible, the usual expectation with VCRs is to get close to (and in front of) the beginning of a video segment, start the playback, finish the segment, and stop the playback. Then cue to the next segment and continue.

- In addition to the list of media devices you have, audio CDs can also be controlled from HyperCard XCMDs. This would allow the addition of CD quality music and/or speech from audio CDs to the presentation. (Please be sure to check copyright issues when using material with copyrights.)

There are a variety of ways to integrate all of these various controllers into one application on the Macintosh. HyperCard XCMDs exist for the VCRs, laser discs, and for MIDI. Using a HyperCard stack that has access to all of the XCMDs would be able to control all of the devices at the click of a HyperCard button.

MacroMind Director 2.0 can use XCMDs from HyperCard, as well as its own XObjects. Thus, you can control the list of devices from within a Director movie, much like you would from within a HyperCard stack.

2) Many of the video boards can send Macintosh images to videotape in the PAL format. Truevision NuVista cards, several RasterOps Cards, and Mass Microsystems cards are all capable of providing PAL output. Some of these cards require an external encoder box to provide the PAL connection. Please check with the manufacturer for exact configurations. The Display Cards 8/24 and 8/24 GC will be able to provide PAL output via Truevision's VIDI/O Box. Eventually, RasterOps will have a PAL version of their Video Extender that will provide PAL.

The Tech Info Library article titled "Locating Vendor Information" can help you search for a particular vendor's address and phone number.

Article Change History:

22 Dec 1995 - Updated LaserDisc XCMD availability, updated format.

QuickTime Streaming: Server Requirements

This article provides the hardware and software requirements for the QuickTime Streaming server and the client workstations.
This article has been archived and is no longer updated by Apple.
QuickTime Streaming is very processor intensive. Therefore, the computer being used as the server should be dedicated as much as possible to streaming. It should also be the highest performance processor available for use.

The minimum configuration is:

- Power Macintosh G3 or Macintosh Server G3
- At least 256MB of memory
- At least 1GB of free disk space
- Software update to Mac OS X
- QuickTime Streaming Server 1.0

The recommended configuration is:

- 400 MHz Macintosh Server G3
- 1GB of memory
- 9GB of free disk space (three ultra-wide SCSI disk drives)
- 4-port Ethernet card
- Software update to Mac OS X
- QuickTime Streaming Server 1.0

AAdditional information is available from the Mac OS X Web site at **http://www.apple.com/macosx/server/qtstreaming.html**

Client workstations should be a PowerPC-based computer with at least 32 MB of memory, running Mac OS 8.0 or higher, and have QuickTime 4.0 or later installed. A static IP or DHCP address is also required because MacIP is not supported.

DHX User Authentication Module 1.0: Read Me

This article comprises the DHX User Authentication Module 1.0 Read Me.
This article has been archived and is no longer updated by Apple.
DHX User Authentication Module 1.0 Read Me

CONTENTS

Introduction

Requirements for Running the DHX UAM 1.0

Installing the DHX UAM 1.0

Using the DHX UAM 1.0 Algorithms used

Known Incompatibilities and Limitations

Introduction

The DHX (Diffie-Hellman Exchange) UAM provides a relativly secure way to transport cleartext passwords of up to 64 characters to the server for further processing.

Requirements for Running the DHX UAM 1.0

AppleShare Client: 3.8.1 or later

Installing the DHX UAM 1.0

The UAM should be placed in a folder titled "AppleShare Folder" within the extensions folder on the current System Folder. No reboot is needed, though you must close the Chooser & Network Browser and reopen them before the new UAM will be noticed.

Using the DHX UAM 1.0 If the server you are connecting to, supports the DHX UAM, the AppleShare Client will put up a dialog allwing you to choose "Encrypted Password" as a login mechanism. Select this UAM and fill in your password and username just as you would for the standard AppleShare login dialog.

Algorithms Used

```
password is padded with nulls to 64 bytes

username is a pstring, padded to even byte length (odd number of chars)

ServerSig is obtained from the AFPSrvrInfo reply from the server.

first message from client to server:
| login (2 bytes)  | AFP Vers | UAMName "DHCAST128" | Username (padded) | Ma (16 bytes) |

reply (server to client)
| ID (2 bytes) | Mb (16 bytes) | (16 byte nonce, ServerSig)K |

login continue (client to server)
| logincontinue (2 bytes) | ID (2 bytes) | (16 byte nonce + 1, password)K |

reply (server to client)
pass / fail

(data)K = Encrypt data using CAST 128 CBC with key = K

The Key is generated with a Diffie-Hellman key exchange as follows:

Ma - first message = g^Ra mod p  (sent by the Client to the Server)

Mb - second message = g^Rb mod p (sent by the Server to the Client)

K - Key = Mb^Ra mod p = Ma^Rb mod p

We are using CAST 128, (the implementation from SSLeay) in CBC mode with the IV in the second message being
the bytestring "CJalbert" and the IV in the third message being the bytestring "LWallace".
```

Known Incompatibilities and Limitations

TA43945_DHX_User_Authentication_Module_Read_Me.pdf

- There seems to be a problem between Norton Antivirus and the DHX UAM. The client Mac will crash with an illegal instruction when the user types into the username or password fields. Workaround is to turn off Norton Antivirus.
- For debugging purposes, there is a debug break before each Alert put up by the UAM, just type g and return in MacsBug. If an alert does not come up, please report it as a bug.

Published Date: Feb 18, 2012

TCP/IP Options: Can‘t Turn Off "Don‘t Retain DHCP lease"

The TCP/IP Options control panel that comes with MacOS 8.6 contains a new check box for "Don't retain DHCP lease on shutdown." This article provides a workaround for a situation where once you turn this on, you can't turn it off.
This article has been archived and is no longer updated by Apple.
TCP/IP Options is an additional control panel that adds functionality not in the standard TCP/IP control panel. For full information on the options available in this control panel, refer to the following TIL articles:

Article 21075: "**TCP/IP Options Control Panel Read Me**"

Article 30994: "**TCP/IP Options: What does "Don't retain DHCP lease on Shutdown" do?**"

There is a known issue with the current version of the control panel which makes it impossible to disable the checkbox for "Don't retain DHCP lease on shutdown." Once the check box is turned on and saved, you will be able to uncheck it, but the changes are not saved. If you close the control panel and reopen it, the check box is still checked.

To revert to the original 8.6 behavior of maintaining lease information across reboots, you will need to do one of the following:

- Trash the TCP/IP Preferences in the Preferences folder.
- To save other TCP/IP configurations you may have, use the "Configurations" dialog box to delete the configuration with the changed prefs and create a new DHCP configuration.

If you wish to change between the two different settings often, create two different configurations in TCP/IP, one for each setting. Then, simply switch between the two TCP/IP configurations rather than using the TCP/IP Options control panel.

Mac OS X Server 1.x: How to Repair an HFS Plus File System

This article details the method to run DiskFirstAid.app to repair Mac OS Extended format (also known as HFS Plus) file systems.

This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If the computer has an abnormal shutdown you should first check all file systems that are attached to the computer. For more information on how to repair the UFS filesystems, please see article 24501: "**Mac OS X Server: Why, When, and How to Run fsck for File System Maintenance**"

Mac OS X Server comes with a program named DiskFirstAid.app that can be used to repair an Mac OS Extended format file system. The program is started from the Workspace Manager by selecting it from the Apple Menu under Server Administration. When the program starts, you simply select the file system graphically and then choose either Verify or Repair.

The most common difficulty that is encountered when running DiskFirstAid.app is that an error message appears stating that the file system could not be unmounted because files are open. If you get this error, make sure you quit all active applications and then use the Remote Admin to stop the Apple File Server. At this point you should be able to successfully run DiskFirstAid.app and then restart the services you shut down.

Novell Netware: AARP Packet Size Error Fix Available

I am running AlisaShare and, on another part of the network, Novell File Servers with Netware 2.15c and the Mac VAP 1.1.

The problem is with the AARP packet size that the Novell file servers are sending. AlisaShare is reporting an AARP packet size error.

I have checked out the AARP packet sizes with a sniffer. AlisaShare thinks the only valid AARP size is 60 bytes. Netware is sending AARPs that are 74 bytes in size. The old versions of Netware (2.15a with Mac VAP 1.0) send ARPs with a packet size of 60 bytes. They work fine with AlisaShare.

This article has been archived and is no longer updated by Apple.
There is a maintenance release of Netware for the Macintosh specifically designed to resolve the AARP packet length problem. You can get it by calling Novell Tech Support and asking for maintenance release 1.11 of Netware for the Macintosh.

For more information, search under: "Novell"

Mac OS X Server 1.x: Manually Configuring for IP Routing

This article tells how to configure Mac OS X Server to route IP among several interfaces.
This article has been archived and is no longer updated by Apple.
Routing is active when the /etc/routed daemon is running. This daemon is start by the /etc/startup/0800_Network script if the proper settings are made in the /etc/hostconfig file.

When you run the Setup Assistant and configure multiple IP interfaces, it asks for an IP address for a router. You should enter the IP address of your router in this space, but then must manually replace it by editing the /etc/hostconfig file.

After the computer has restarted, open a Terminal window and use vi to edit the /etc/hostconfig file. The file this line:

```
ROUTER=1.2.3.4
```

If you have followed the steps above it should be set to point at the IP address of the router you entered in the Setup Assistant. Change the line to look like this:

```
ROUTER=-ROUTED-
```

Now when you restart the computer the startup scripts automatically start routed. If you want to change to parameters that are supplied to routed you must edit the /etc/startup/0800_Network script and change the -q parameter in this section:

```
case ${ROUTER:=-NO-} in

     -ROUTED-)
       # Set the 'q' (quiet) flag by default to avoid broadcasting routes.
       echo "     Using routed"
       routed -q
       ;;
```

For example if you wanted to have a -s parameter you would change the -q to -s and the final result would look like this:

```
case ${ROUTER:=-NO-} in

     -ROUTED-)
       # Set the 's' flag to force routed to supply routing information
       echo "     Using routed"
       routed -s
       ;;
```

A description of the valid parameters to routed and how what they mean is available in the routed man page. Access this page through the Terminal.app with the command 'man routed'.

Power Macintosh G3 (Blue and White): Mac OS Version Misprinted on Some CDs

Some Software Install or Restore CDs that came with Power Macintosh G3 (Blue and White) computers mistakenly state the system software version as 8.6.1.
This article has been archived and is no longer updated by Apple.
This is a misprint on a limited number of the CD-ROM discs, part number 691-2321. The actual version of the Mac OS on the CD is 8.6, there is no version 8.6.1.

This misprint also affects the Macintosh Server G3 CD part number 691-2322, as well as the SoftRaid CD part number 691-2329.

New CDs are being introduced into the Accessory Kits with the correct Mac OS version listed.

PowerBook G3 Series (Bronze keyboard): Sources for Additional Assistance

My PowerBook G3 Series (Bronze keyboard) came with two manuals. Where do I go to find answers to common questions that are not answered in these manuals?

This article has been archived and is no longer updated by Apple.

The PowerBook G3 Series (Bronze keyboard) comes with two printed manuals; Getting Started With Your PowerBook and Troubleshooting Handbook. If you cannot find your answer in these two manuals, here are some additional resources available to you.

Help Center

Selecting Help Center in the Help menu will present you with the available Help Guides installed on your PowerBook. At a minimum you should see "About Your PowerBook" and "Mac OS Help."

About Your PowerBook

The About Your PowerBook guide will give details about your specific computer. It will help you find out how to use features, connect external peripherals, install memory, and more.

Mac OS Help

The Mac OS Help guide will help you with such tasks as connecting to the Internet, setting up to print, and learning what's new in the Mac OS.

Internet

Other help systems are available via the Internet. The Apple Support Web site problem solving page is availabe at http://www.info.apple.com/support/powerbook/solve.html.

For news and specifications specific for PowerBook users go to http://www.apple.com/powerbook. For information on Macintosh products by Apple and other companies see http://www.apple.com/guide.

Mac OS 8.6: USB Printer Compatibility

This article discusses the enhanced USB printer support in Mac OS 8.6, as well as listing various USB printer models.

You may also wish to review article 43027: "**Connecting a Serial Printer to a USB Capable Macintosh**" for more information on connecting a variety of printers to a USB enabled Power Macintosh or PowerBook.
This article has been archived and is no longer updated by Apple.
Mac OS 8.6 running on USB-equipped Macintosh computers, such as the iMac, iBook, PowerBook G3 Series (Bronze keyboard), Power Macintosh G3 (Blue and White) and Power Mac G4, supports printing to both USB inkjet and now USB-compatible PostScript printers. Below is a list of printers the printer manufacturers informed Apple were compatible with Mac OS 8.6 at the time Mac OS 8.6 was released.

Many of these printers have USB ports built-in, whereas others do not and require an adapter. Inkjet printers require printer drivers from the printer manufacturer.

Note: Mac OS 8.6 includes LaserWriter 8 version 8.6.5 which adds support for printing to USB-compatible PostScript printers. LaserWriter 8.6.5 provides support for PostScript printers that have USB ports built-in, and those that have IEEE 1284 parallel compatible ports. IEEE 1284 compliant printers may be connected to your Macintosh via a USB-to-Parallel adapter cable. The Infowave PowerPrint adapter is an example of such an adapter cable that may work with your PostScript printer having a parallel port.

The following list is not inclusive of all available compatible USB printers. Please check with your printer manufacturer for updated drivers and current compatibility information.

Macintosh Server G3 (Blue and White): Unsupported Monitor Resolution

My Macintosh Server G3 (Blue and White) with Mac OS X Server Technical Information manual states that the highest monitor resolution supported is 1920 x 1200. However, this resolution does not show up in my Monitors & Sound control panel. Is this a supported resolution?
This article has been archived and is no longer updated by Apple.
The 1920 x 1200 monitor resolution is not supported by any of the Macintosh Server G3 (Blue and White) models.
Published Date: Feb 18, 2012

PowerBook G3 Series (Bronze keyboard): SCSI ID Setting in PowerBook SCSI Setup Control Panel

When using HD Target Mode after performing a clean installation of system software on a PowerBook G3 Series (Bronze keyboard), the SCSI ID of the PowerBook is set to 2 regardless of the setting in the PowerBook SCSI Setup control panel.
This article has been archived and is no longer updated by Apple.
This issue arises in the Mac OS ROM file version 1.4 which is part of the Mac OS Install on the Restore CD included with your PowerBook. Since Apple has shipped all PowerBook G3 Series (Bronze keyboard) computers with Mac OS ROM version 1.6 pre-installed, this situation arises only after performing a clean installation.

If you run the Mac OS Install instead of the Apple Software Restore, you must install the 1.6 version of the Mac OS ROM. The Mac OS ROM version 1.6 file is contained in the Important Extra System Software folder on your PowerBook G3 Series CD that accompanies your computer.

After performing a clean installation using the Mac OS Install, copy the Mac OS ROM file, along with the other items in the folder, into your System Folder and restart. After restarting, you can set the SCSI ID in the PowerBook SCSI Setup control panel as you normally would.

For additonal information on this folder see the following:
Article 58352: "**PowerBook G3 Series (Bronze keyboard): About Important Extra System Software Folder**".

DayStar FastCache: Incompatible with Apple Tape Backup

Apple Tape Backup 2.0.1 crashes when running on my Macintosh IIci whenever a DayStar Digital FastCache card is physically installed in the Macintosh.

This article has been archived and is no longer updated by Apple.
DayStar Digital confirmed that Apple Tape Backup does not run with cache turned on. The only current workaround (June, 1990) is to turn the cache off when running Tape Backup.

Please note that removing the DayStar FastCache Macintosh IIci CDEV will not turn cache off, since it is controlled in ROM. The correct way is to leave the DayStar CDEV in the System Folder, choose Control Panel from the Apple menu, click the DayStar FastCache Macintosh IIci CDEV, and turn the cache off.

Power Mac G4 (AGP Graphics): Maximum Energy Savings Depends on PCI Cards

This article explains how Power Manager 2.0 can save energy by turning off Peripheral Component Interconnect (PCI) cards installed in a Power Mac G4 (AGP Graphics) computer.

This article has been archived and is no longer updated by Apple.

Power Manager2.0 can turn off the PCI cards installed in a Power Mac G4 (AGP Graphics) computer. Turning off the PCI cards when the computer is in sleep allows it to save energy. With all the PCI cards turned off, the cooling fan can also be turned off providing more power savings.

To get the most energy savings, all PCI cards installed in the computer must allow Power Manager2.0 to turn them off. Some PCI cards are designed to be turned on when the computer is turned on. If one of these kinds of cards is installed, Power Manager2.0 does not turn it off, and the computer's cooling fan continues to run when the computer is in sleep.

If your Power Mac G4 (AGP Graphics) does not turn off its cooling fan when in sleep, check with the vendors of the PCI cards installed in your computer to find out if they are compliant with Sleep Manager 2.0, or if they can be upgraded to be compliant.

Power Mac G4: Description of Velocity Engine

This article describes the Velocity Engine, also known as AltiVec, which is incorporated into the new PowerPC G4 processors in the Power Mac G4 computer.
This article has been archived and is no longer updated by Apple.
The Velocity Engine can process data in 128-bit chunks, instead of the smaller 32-bit or 64-bit chunks used in traditional processors (it's the 128-bit vector processing technology used in scientific supercomputers--except that we've added 162 new instructions to speed up computations). In addition, it can perform four (in some cases eight) 32-bit floating-point calculations in a single cycle--2-4 times faster than traditional processors.

The PowerPC G4 with Velocity Engine works with the PowerPC architecture to accelerate the data-intensive processing required by next-generation video, voice, and graphics applications. Among the G4 key features is a vector permute function capable of rearranging data in the registers--a priceless benefit when converting data from one format to another (often necessary with voice, video and graphics apps, which typically need to save data in a number of different formats). These vector processing acceleration advantages give the G4 microprocessor a significant edge when it comes to fast visualization of large data sets, and intensive math for real-time simulations. Making the G4 perfect for everything from graphics and 3D games to astronomy, the biosciences, and predictive modeling.

For an in-depth discussion of the technology, refer to the Motorola Web page on AltiVec at
http://www.mot.com/SPS/PowerPC/AltiVec/index.html

TA43967_LaserWriter_IINTX_ROMs_Are_v_as_of_June__(TIL05845).pdf

LaserWriter IINTX: ROMs Are v3.0 as of June, 1990

Have the LaserWriter IINTX ROMs been updated to allow software switching back from LaserJet to PostScript? My LaserWriter IINTX manual says you can get the software to switch back, but I am unable to make it work.

This article has been archived and is no longer updated by Apple.
LaserWriter IINTXs (controller board Apple part #M6004/A) are currently shipping with version 3.0 ROMs. The major differences between these and older ROMs are:

- Software switching from LaserJet emulation to PostScript
- Font cleanup in LaserJet emulation
- Better disk management routines
- PostScript 51.8.

The upgrade kit (Apple part #M0445LL/A) is expected to ship (in very small numbers) in the third week of June.

Support Readiness will send upgrade kits (including the new manual) on a one-per-site basis as soon as they are available.

PowerBook 5300 and 190: Troubleshooting No Power On Symptom

This article provides some basic troubleshooting steps for a PowerBook 5300 or 190 that does not power on.
This article has been archived and is no longer updated by Apple.
This process resets both the Power Manager and revives PowerBook 5300 and 190 computers which do not initially turn on.

1. Unplug AC adapter and remove battery.
2. Press and hold the Reset button on the back of the machine for about 45 seconds. (See chart below for location of the reset button.)
3. Plug the AC Adapter into the AC (wall) outlet.
4. Attach only the AC adapter to the PowerBook (don't put in the battery).
5. Press the Reset button one more time and the PowerBook should startup after a brief pause.

PowerBook	**Reset Button Location (on rear of computer)**
190 Series	Below the video out port
5300 Series	Below the video out port

Note: The Power Manager code can be fully purged by having an authorized service technician disconnect the internal backup battery and let the unit sit for 1 minute with all power removed (including the main battery and the AC Adapter). This forces the PowerBook to reload the code from the system software.

Authorized Apple Service technicians may remove the internal back up battery to reset the Power Manager. If you are not an authorized Apple Service technician, please note that removing the internal backup battery is not a simple procedure and is not recommended. If anything is damaged in your attempt to remove the battery, it will not be covered under warranty.

Important Information About Your iMac

This document contains important late-breaking information about your iMac. For additional information, refer to the printed documentation that came with your computer, the online help for your iMac (Mac Help), and information located in the Help menu of most applications. Apple also provides substantial information on the Internet. If you have access to the Internet, you can find the latest information about iMac in the support area at www.apple.com/support/imac

The following topics are covered in this document:

Using your iMac
About the Apple DVD Player
Playing and recording from audio CDs
Adjusting and testing external USB (Universal Serial Bus) speakers
Connecting to a 10/100Base-T network
Connecting your computer directly to an Ethernet switch
Ethernet performance
Formatting external USB hard disk drives
Improving startup time
Setting the resolution when using an external monitor for video mirroring
Using additional alert sounds
Copying and pasting alert sounds
Using your computer with a NetBoot server

Third-party software
Using the internal modem with third-party software
Preserving Bookmarks and Favorites files when reinstalling Internet Explorer and Netscape Communicator
Setting up AOL when the Palm Desktop Software 2.5 is installed
Using EdViewInternet Safety Kit

Hardware compatibility
Using a digital video (DV) camcorder
Using USB devices with software applications
Connecting and disconnecting USB devices while the computer is asleep
Mounting and disconnecting USB storage devices
Using ADB copy-protection dongles
Using USB-to-serial converters

Documentation changes
Mac Help instructions for modifying a remote access configuration
References to Monitors & Sound Control Panel in Mac Help

Using your iMac

About Apple DVD Player
Apple included a preview version of Apple DVD Player software on iMacs that include a built-in DVD-ROM drive. This software ships as part of the Mac OS 8.6 version included with your iMac computer and is not compatible with the DVD hardware found in the Power Macintosh G3, PowerBook G3, and Power Mac G4 (PCI graphics) series computers. Apple expects to make an updated version available soon. For the latest information about the Apple DVD Player software and answers to support questions, go to Apple's Support Web site at www.apple.com/support

Playing and recording from audio CDs
Audio CD playback is now digital for increased fidelity and use with digital audio peripheral devices. When you play audio CDs, you no longer need to select "Internal CD" in the Input section of the Sound control panel or the Sound section of the Control Strip. However, to record from an audio CD, you may still need to select "Internal CD" in the Input section of the Sound control panel or the Sound section of the Control Strip.

Adjusting and testing external USB (Universal Serial Bus) speakers
The Speaker Setup section of the Sound control panel allows you to select and change the settings of the USB speakers connected to your computer. Use the Speaker Setup panel to select which speakers you want to use and to adjust the relative volume for each speaker. For example, if you have a subwoofer connected to your computer and want to adjust the volume for the subwoofer only, use the slider underneath the subwoofer to change the volume.

You can also test the speakers connected to your computer by clicking Start Test in the Speaker Setup section. The computer plays a "white noise" test tone on each speaker, allowing you to adjust the relative volume of that speaker. The "white noise" test tone contains sound for all

frequencies and sounds like static. You may want to reduce the overall sound volume for your computer using the Output section of the Sound control panel before testing your speakers, as the test tone can be quite loud on some speakers.

Connecting to a 10/100Base-T network
When you connect your iMac to an Ethernet network, the computer automatically senses whether it is connected to a 10Base-T network or to a 100Base-T network. Some (possibly all) ports on some network hubs/switches support both speeds. If you're using this type of hub/switch, there may be a delay in establishing a network link. The delay may last for several seconds after you start or restart the iMac and a message may appear saying the network is not available or that the network has only just become available. If you don't want a delay, connect your computer to an Ethernet network port that is not auto-sensing (10 or 100 megabits per second (Mbps) only). For more information, contact the manufacturer of the Ethernet hub/switch or your network administrator.

Connecting your computer directly to an Ethernet switch
If you connect your iMac directly to an Ethernet switch, you must disable spanning tree on that port. Otherwise your computer could duplicate the AppleTalk address of another computer on the same network and both network connections would become unreliable.

Ethernet performance
Your computer performs best when the Ethernet port is set to auto-negotiate. If you experience performance problems on your Ethernet network, check with your network administrator.

IMPORTANT The duplex mode of an Ethernet link to a switch is not detected if the port is not auto-negotiating. In this case, your computer will detect the appropriate speed but will default to half-duplex. If the port at the other end of the link is configured for full-duplex, a large number of late events can occur on the link. Set the switch's port to auto-negotiate where possible. If this isn't possible, then set the switch's port to half-duplex. For more information, see the documentation that came with the Ethernet switch.

Formatting external USB hard disk drives
Many USB hard disk drives are preformatted for use with DOS. You can use DOS-formatted USB hard drives with your computer, but you can get better performance if the USB hard drive is reformatted using Mac OS Extended or Mac OS Standard formatting.

Improving startup time
For best performance, make sure that a valid startup disk is selected in the Startup Disk control panel. If an invalid startup disk is selected (one your computer cannot start up from), your computer could take as long as two minutes to locate a valid startup disk and properly start up. PC card devices and RAM disks are examples of invalid startup devices, even though their icons may appear in the Startup Disk control panel.

If you have selected a CD as the startup disk in the Startup Disk control panel, and you start up your computer without a CD, or with a CD other than the software install or software restore CD that came with your computer, a single folder with a reappearing question mark appears on the screen. The computer will search for a System Folder and start up. If no System Folder is available, you must insert the software install or software restore CD that came with your computer and restart your computer. If you don't want to start up from a CD, make sure you choose another disk, such as the hard disk, as the startup disk in the Startup Disk control panel.

Selecting the Network Disk icon in the Startup control panel without having a Netboot server properly set up will also significantly delay the time it takes your iMac to start up.

Setting the resolution when using an external monitor for video mirroring
When you connect an external monitor to your computer for video mirroring, the external monitor uses the same resolution and timing as your computer. In order to properly view what's on the computer's screen on the external monitor, you must use one of the following resolutions:
Mode/Vertical refresh rate
- 640 x 480, 117 Hertz (Hz)
- 800 x 600, 95 Hz
- 1024 x 768, 75 Hz

To change the resolution:
1. Open the Apple menu, select Control Panels, then choose Monitors.
The Monitors control panel opens.
2. If necessary, click the Monitors button.
3. Click the desired resolution on the right, then click the close box to close the control panel.
Your computer and the external monitor are set to the desired resolution.

Note: If the external monitor isn't working, try changing the resolution to 1024 x 768, 75 Hz.

Using additional alert sounds
Your iMac includes resampled sounds which take advantage of the high-quality speakers in your computer. These sounds are located in the Additional Alert Sounds folder within both the Apple Extras folder on the hard drive and the CD Extras folder on the iMac software install CD. To install the alert sounds, quit all applications, and drag the desired files from the Additional Alert Sounds folder, onto the System Folder on your hard disk. The files will automatically be installed into the System file and available for use by all applications.

Copying and pasting alert sounds
Long alert sounds require large amounts of memory. If you have difficulty copying and pasting long alert sounds into the Sound control panel, you may need to adjust memory requirements for the control panel. To do this, open the Control Panels folder within the System Folder. Select the

Sound control panel, choose Get Info from the File menu, and then choose Memory in the Show pop-up list. Increase the preferred memory size, close the Get Info window, and try again until the preferred memory setting allows you to copy and paste the long alert sound.

Using your computer with a NetBoot server
If you want to use your iMac as a NetBoot client, you will need to update the system on the NetBoot server. For more information and instructions, go to the Mac OS X Server Web site at www.apple.com/macosx/server or the Apple Support Web site at www.apple.com/support.

Third-party software

Using the internal modem with third-party software
Some third-party software, such as FaxSTF or Total Access, have different modem selections than the ones found in the Modem control panel. Using these selections can slow down your connection speed. To use these programs with your computer's internal modem at its highest speed, make sure you select Apple Internal 56K Modem (V.90) in the Modem control panel.

Preserving Bookmarks and Favorites files when reinstalling Internet Explorer and Netscape Communicator
If you inadvertently delete the Internet Explorer or Netscape Communicator applications, you can reinstall the applications using the software install CD that came with your computer. Apple recommends that you move the file that contains your Internet sites list to a different location, such as the desktop, so that you can restore it after reinstalling the software. For Internet Explorer, this file is Favorites.html; for Netscape Communicator, the file is Bookmarks.html. When you reinstall Internet Explorer or Netscape Communicator, the program overwrites the sites list file; any locations or bookmarks that you added or that were preinstalled will be lost.

Setting up AOL when the Palm Desktop Software 2.5 is installed
If you installed the Palm Desktop Software 2.5 on your computer and you attempt to setup AOL, there is a conflict and a message may appear saying you have a "port in use" error. You need to disable HotSync so you can properly set up AOL. To do this, open HotSync Manager (click the icon next to the Applications menu, choose HotSync, and in the pop-up menu, select Setup). If necessary, click the HotSync Controls tab. In the HotSync section, click the button next to Disabled. AOL is aware of this issue and expects to make an update available soon. For the latest information about AOL updates, log into AOL and enter the keyword UPDATE.

Using EdView Internet Safety Kit
The version of EdView Internet Safety Kit that comes with your iMac is not compatible with the current version of Sherlock. Using Sherlock with EdView may cause a system freeze that will require you to force restart your iMac. To force your iMac to restart, simultaneously hold down the Control and Command keys, then press the Power button on the front of the computer.

Hardware compatibility

Using a digital video (DV) camcorder
Some DV camcorders may not be recognized immediately when you connect them to one of your iMac's FireWire ports. If your computer does not recognize your DV camcorder, try turning the camcorder off and then on again to establish a connection. If you continue to have problems, contact the manufacturer of the DV camcorder.

Using USB devices with software applications
Some applications don't recognize a USB device if the device is plugged in while the application is already running. To use the USB device with that application, quit the application, make sure the device is properly plugged in, then start the application again.

Connecting and disconnecting USB devices while the computer is asleep
When you connect and disconnect a USB device to and from your computer while the computer is in sleep mode, your computer automatically wakes up.

Mounting and disconnecting USB storage devices
To mount or remount a USB storage volume on the desktop, disconnect and then reconnect the device that contains the volume to a USB port on the computer, or to a USB hub attached to your computer. The volume should appear on the desktop in a few seconds. If the device uses removable media, the volume will not appear until the removable media is reinserted into the USB storage device.

Before you disconnect a USB storage device from your computer, close all open windows and quit all running applications that are stored on the USB storage device. If the device has a manual eject drive (you eject the removable media from the device yourself), make sure you eject the removable media first. Do not disconnect the device from your computer until a message appears saying it is safe to do so. Drag the device's icon to the Trash on the Desktop, then disconnect the device from your computer.

Using ADB copy-protection dongles
Some applications require the use of a ADB (Apple Desktop Bus) adapter for security purposes to prevent software piracy. The iMac uses Universal Serial Bus (USB) technology. You may be able to use a USB-to-ADB adapter with these applications in order to use an ADB copy-protection dongle. For more information, contact the software manufacturer.

Using USB-to-serial converters
You may be able to use some serial devices such as modems, printers, and digital camcorders with your iMac using a third-party USB-to-serial converter adapter. However, not all serial devices may be compatible with such an adapter. For more information, contact the adapter manufacturer.

Documentation changes

Mac Help instructions for modifying a remote access configuration
The instructions for editing Remote Access settings provided in Mac Help are incorrect. When you are asked to choose Automatic, you must select PPP or ARAP, because there is no longer an Automatic setting.

References to Monitors & Sound Control Panel in Mac Help
There are several references to the Monitors & Sound control panel in the online help (Mac Help). In the current version of Mac OS installed on your computer, the Monitors & Sound control panel has been divided into two separate control panels-a Monitors control panel and a Sound control panel. For specific help, click the question mark button in either control panel.

Published Date: Feb 18, 2012

iMovie 1.0: Read Me

This article contains the Read Me for iMovie.
This article has been archived and is no longer updated by Apple.
Editor's Note: iMovie 1.0 only comes with iMac DV computers. iMovie 1.0 is not a separate retail product. It is only supported on iMac DV computers.

About iMovie 1.0
Welcome to iMovie, an application that integrates Digital Video (DV) capture, scene editing, titling, transition effects, and audio to create broadcast-quality movies. For a list of qualified camcorders and DV devices, see the Device Compatibility section below. For the latest news and information about iMovie, visit the iMovie web site at www.apple.com/imovie

System Requirements

- A Power Macintosh computer with a PowerPC G3 300 MHz or faster processor*
- Mac OS 8.6 or later
- QuickTime 4.0 or later
- 64 megabytes (MB) of random access memory (RAM). iMovie requires a minimum of 16 MB free. On systems with 64 megabytes, be sure Virtual Memory is turned on in the Memory control panel.
- A CD-ROM drive
- 2 gigabytes (GB) of available hard disk space highly recommended
- A display that supports 800 x 600 resolution and thousands of colors (1024 x 768 in millions recommended)
- A built-in FireWire (IEEE1394) port
- A 4-pin to 6-pin FireWire cable (for use with DV camcorder)

*Compatibility with older computers is limited.

Getting Started
When you first open iMovie, create a new project. If you want to take a tutorial to get familiar with iMovie, Open the Help menu and choose iMovie Tutorial.

Reinstalling iMovie
To reinstall iMovie, open the installer on the iMovie CD and follow the instructions on the screen. The application and components will be placed in a folder named iMovie on the main level of your hard disk.

Note: iMovie was installed on your computer in the Applications folder on your hard disk. The Installer will put an iMovie folder containing the iMovie application folder and or the iMovie Tutorial folder on the main level of your hard disk. After installation, drag this folder and its contents into the Applications folder to restore it to the original location.

Application Notes

For Optimal Performance When Running iMovie
Quit any applications that may be running in the background. iMovie should be the only active application. On 64 megabyte computers, be sure Virtual Memory is turned on in the Memory control panel. Do not switch monitor resolutions while rendering is active.

These file formats are supported for input:
Still images: PICT, JPEG, GIF, BMP, and Photoshop
Audio files: AIFF and CD audio tracks
QuickTime movies: DV Stream format only

These file formats are supported for output:
QuickTime movies
Still images: PICT and JPEG
Video to DV tape
Do not unplug DV devices during import or export processes.

Font support:
The titling feature in iMovie supports TrueType as well as Adobe PostScript fonts.

16:9 Format
iMovie does not work with clips with a 16:9 aspect ratio.

Capturing Live Video From a Camera
If you intend to capture live video from a camera:

1. Switch the camera to Camera mode and set the Lock/Standby switch to Standby.
2. Remove any tape cassettes in the camera. A tape in the camera will cause the camera to time out and go into sleep mode. If the camera requires a tape to be in the camera but does not play video through to iMovie, check that the tape's write protection tab is unlocked.
3. Make sure the camera's demo mode is disabled. Some cameras switch to a demo mode when left on standby without a tape inserted. Check for a demo function in your camcorder's settings menu and disable it.

Renaming Clips
You can rename clips within iMovie. However, do not change the name of clips in your project folder. This will break links to the media in your project file.

Ejecting DVDs and CD-ROMs
Eject DVDs or CD-ROMs prior to running iMovie by dragging the disc icon on the Desktop to the Trash. If you are in iMovie, choose Hide iMovie from the Application menu in the upper right corner of your screen to switch to the Finder. Eject your DVD or CD-ROM while in the Finder, then choose iMovie from the Application menu to resume editing.

Maximum Movie and Clip Size
The maximum length of a movie is limited only by the available disk space on your computer. There is no limit to the number of clips that can be combined to create a single movie. However, the maximum file size of an individual movie clip is 2 gigabytes. If you exceed this 2 gigabyte limit during an extended duration capture, iMovie will continue the capture into a second clip.

Working While Rendering
You can continue working in a project while rendering transitions or titles. Performance may decline if you have more than two render processes working simultaneously.

Emptying the Trash Resets the Undo Command
If you empty the trash in iMovie, you will not be able to undo any actions taken prior to emptying the trash.

Sound Input
Do not change the sound input device while iMovie is running. iMovie uses an external or built-in microphone as the sound input device to record your voice. If you need to switch to one of these devices, quit iMovie then select the device in the Sound control panel or from the Control Strip.

Do Not Capture Video to Storage Devices Over A Network
Capture video to projects on local hard disks. Do not capture video to projects saved on a server. Video cannot be reliably captured over a network to a project stored on a server.

Simultaneous Use of Multiple DV Devices is Not Supported
iMovie will not work with more than one DV device connected to your computer with FireWire.

QDesign Music Codec 2 Professional Edition Sound Compression
If you plan to use this sound compression software with iMovie, you must first export a movie through QuickTime Player using this codec and register the software with its serial number when prompted. You can then proceed to export movies with QDesign Music Codec 2 sound compression through the Expert export settings in iMovie.

Tutorial Notes

Removing and Restoring the Tutorial Project and Media Clips
You can reclaim hard disk space by removing the Tutorial project and media. Drag the iMovie Tutorial folder to the Trash in the Finder and choose Empty Trash from the Special menu. To restore the Tutorial project with its source media, insert the iMovie CD into your CD-ROM drive. Double-click the Install iMovie icon. Follow the onscreen instructions and when you reach the Custom Installation and Removal panel, choose iMovie Tutorial (160 MB).

Leave the box labeled iMovie (20 MB) unchecked. After completing the installation, open the iMovie folder on your hard drive and drag the iMovie Tutorial folder onto the iMovie folder in the Applications folder. Throw away the iMovie folder on the main level of your hard disk.

Note: The iMovie Tutorial folder must be inside the iMovie folder, alongside the iMovie application folder, in order to work with the tutorial instructions in the Help menu.

PAL Support for the Tutorial
iMovie supports PAL format video. However, the media created for the tutorial is in NTSC format and cannot be exported to PAL format DV devices.

Troubleshooting
Audio Dropout in Movies Exported to Tape
If you experience audio dropout in a movie that you have exported to tape, return to your project and lower the volume level of the affected clip with the volume slider in the audio viewer. Then re-export your movie.

Lack of Video in Capture Mode
If you can control your camera, but do not receive a video feed to the monitor in camera mode, disconnect the FireWire cable while your camcorder is still on, then reconnect the cable.

PAL Support - Video Standard of Camera Doesn't Match Video Standard of Project
Before you create a project, connect and turn on your camcorder. If you are using a PAL format DV camcorder, iMovie will recognize the device and create the project in PAL format.

Cannot Export a Movie to a PAL Camcorder
If you can not record to your PAL camcorder, check the manufacturer's specifications for your device. Certain PAL devices have FireWire (IEEE1394) input disabled.

Device Too Slow Alert When Using FireWire Storage Devices with iMovie
Go to the manufacturer's website and download the latest device driver. Install and restart your computer, then restart iMovie.

Running Low on Memory
On computers with 64 megabytes of memory, be sure Virtual Memory is turned on in the Memory Control Panel. Quit any applications that may be running in the background other than iMovie. Increase the amount of memory allocated to iMovie by doing the following.
1) Quit iMovie.
2) Locate the iMovie application (not the alias) and click once on the iMovie application icon.
3) Open the File menu and choose Memory from the Get Info submenu.
4) Increase the number in the Preferred Size field to 30720 then close the window and restart iMovie.

Discrepancy Between Playhead Reading at End of Clip and Clip Duration
There is a one-frame difference between the duration of a clip and the playhead reading when the playhead is parked on the last frame. This is normal and will not affect your project.

Cannot Throw Away iMovie Resource Files
If you experience trouble throwing away iMovie resource files, select the files and choose General Information from the Get Info sub menu in the File menu. Check the box labeled Locked at the bottom left corner of each window then close each info window. Choose Empty Trash from the Special menu.

Device Compatibility
The following DV devices have been qualified for use with iMovie. For the latest information on DV device compatibility, visit the iMovie web site at www.apple.com/imovie

Sony Models
DVMC-DA1 and DVMC-MS1 AV adapters (Allows use of non-DV devices such as Hi8 and other analog camcorders. However, these devices do not allow iMovie to control the camcorder.)
DCR-PC1
DCR-PC10
GV-D300
DCR-TR7000
DCR-TRV103
DCR-TRV110
DCR-TRV310
DCR-TRV310E
DCR-TRV5E
DCR-TRV510
DCR-TRV7
DCR-TRV8
DCR-TRV9
DCR-TRV9E
DCR-TRV900
DCR-TRV900E

AG-EZ30
PV-DV710
PV-DV910

*Sharp Models
VL-PD3

***Tips For Camcorders With Compatibility Issues.**

Canon Camcorders
If you cannot pause the camera during rewind or fast-forward in iMovie, try again, or press the Stop button instead of the Pause button.

Panasonic Camcorders
If you attempt to export to tape and the camcorder LCD flashes the message "Check DV Input" then enters REC/Pause mode, but never actually starts recording, do the following:
1. Stop the camcorder and cancel the export.
2. Add a few extra seconds of black before the recording, or increase the time to wait for the camera in the Export Movie window.
3. When you export to tape, watch for black frames being sent to the camera on the LCD then press the "Still" button on the camcorder's VTR controls to begin recording.

Sharp VL-PD3
If you attempt to export to tape and the camcorder goes into record/pause mode, but never actually starts recording, do the following:
1. Stop the camcorder and cancel the export.
2. Add a few extra seconds of black before the recording, or increase the time to wait for the camera in the Export Movie window.
3. When you export to tape, press the Play button on the camcorder's VTR controls to begin recording.

Storage Device Speed
iMovie needs fast hard disks. When adding more storage devices, you will need disk drives with a sustained transfer rate of 3.6 MB or higher. The following storage devices do not meet the minimum transfer rate or capacity requirements to work with iMovie.
SuperDisk drives
Floppy disk drives
Zip drives
AppleShare or IP mounted file servers

LaserWriter IINTX: Use Font Utility 2.0 with Rev 3.0 ROMs

System: LaserWriter IINTX with Rev 3.0 ROMs (PostScript Version 51.8) and 20MB hard drive attached to SCSI port. Apple LaserWriter Font Utility Version 1.0/ System Software 6.0.5

Problem

When using the Apple Font Utility to download fonts, I downloaded some fonts, stopped and then restarted the process again in the morning. The Apple Font Utility did not show any fonts previously downloaded as appearing on the hard drive. The start-up test page does show that there were 46 fonts available. The Adobe Font Utility also lists all of the available fonts. Only the Apple Font Utility doesn't show them.

I then installed another font and it showed as being there, but none of the others did (this was done without quitting the Apple Font Utility). After quitting the Apple Font Utility and restarting, the fonts don't show. Adobe's utility does show the additional font, as does the startup page.

The fonts do print correctly and the LaserWriter goes to the hard drive and gets the fonts as needed; that is, they DO NOT get downloaded over LocalTalk.

Is there a problem with the Apple LaserWriter Font Utility Version 1.0 and the new LaserWriter IINTX board? Is there a problem with the 1.0 Font Utility and System Software 6.0.5?

This article has been archived and is no longer updated by Apple.
A new version of the LaserWriter Font Utility ships with the new LaserWriter IINTX board. If you have the new board, you should be using version 2.0 of the LaserWriter Font Utility.

iBook & iMac: Improper Wakeup When Started Up From Mac OS 8.6 CD

When an iBook or iMac (Slot Loading) has been started up from the Mac OS 8.6 CD, it will not wake from sleep properly.
This article has been archived and is no longer updated by Apple.
If you start up from the Mac OS 8.6 CD and then put the iBook or iMac (Slot Loading) to sleep (or let it go to sleep by itself), it will not come out of sleep properly. Instead, the hard drive spins up but the screen remains black.

On an iBook you can press Command-Control-Power or press the reset button to recover. On the iMac (Slot Loading), press the reset button on the side of the computer, or press the power button on the computer itself for at least 5 seconds to recover.

This behavior does not occur when starting up from the Mac OS 9 CD.

Power Mac G4: Boot Issue When 1 GB or More of RAM Installed

Apple has identified an issue affecting Power Mac G4 computers with 1 GB or more of RAM installed. After installing the memory, the computer will fail to produce a startup chime and hang during the start up process. This article provides a workaround to this issue.
This article has been archived and is no longer updated by Apple.
When starting up the computer from a powered-off state (such as directly after installing RAM) the computer will fail to produce a startup chime and hang during the start up process. At that point, perform a warm restart by pressing the reset button on the front of the computer and it will reboot successfully.

Note: The startup chime will still not be audible.

Apple is investigating the issue in order to provide a permanent resolution. In the interim, this issue can be avoided by putting the computer to sleep instead of shutting it down.

Published Date: Feb 18, 2012

Power Mac G4 (PCI Graphics): Extended Net Boot Start Up Time

When Net Booting the 350 MHz version of the Power Mac G4 (PCI Graphics), the computer may appear hung due to an extended period of time to start up.
This article has been archived and is no longer updated by Apple.
Note: This issue only affects Net Booting, booting from the internal hard drive is not affected.

When using Net Booting, the computer will display the small system folder icon indicating it is looking for valid system software from which to start up. This icon may be displayed for two to five minutes before the start up process continues.

You may workaround this issue by starting the computer from the internal hard drive instead of using Net Booting.

The root cause is within the BootROM and will be fixed in a future update. This article will be updated at that time, or you may refer to the Apple Software Updates Web site at http://www.apple.com/swupdates.

Published Date: Feb 18, 2012

Mac OS 8.6: Save Name and Password Dimmed in the Chooser

When connecting to an AppleShare file server through the Chooser, the option to save your name and password is dimmed. This condition only occurs on a Power Mac G4 (AGP Graphics), iBook, or iMac (Slot Loading) computer with Mac OS 8.6 and AppleShare client version 3.8.4 .

This article descirbes this issue in detail and provides two workarounds.
This article has been archived and is no longer updated by Apple.
In the Chooser window that reads: "Select the items you want to use:" there is a checkbox to the right of every available volume. When you click the checkbox for any volume, you are given the options to save your name, or save your name and password, as shown in Figure 1. These options save your user log-on information so you do not have to re-enter it each time you automatically connect to the server at system startup time.

Note: The AppleShare file server administrator must allow users to save their names and passwords for that option to be available.

Figure 1 Chooser Window with AppleShare 3.8.3

When using Mac OS 8.6 and AppleShare client version 3.8.4, the second option is "Save My Name and Password in the Keychain" as shown in Figure 2. The name and password option was changed in anticipation of Mac OS 9, but because the Keychain is not installed with Mac OS 8.6, the option to save your name and password is dimmed.

Figure 2 Chooser Window with AppleShare 3.8.4

There are two possible solutions for this issue:

1. Install an earlier version of the AppleShare client software. Version 3.8.3, for example, is available for download from the Apple Software Updates Web site at http://www.apple.com/swupdates.

2. Upgrade to Mac OS 9.

Business BASIC III: RENUMBER -- Unreferenced Lines

This article has been archived and is no longer updated by Apple.

Business BASIC's RENUMBER program isn't able to properly renumber the sample program:

```
10 GOTO 20
```

Though it's obvious that GOTO 20 references a line that doesn't exist, it won't always be obvious in a large program. One way to check that there are no "phantom" line numbers is to use the XREF function in the RENUMBER program before you actually renumber your program.

Radius Pivot Card: Display Card 8/24 GC Compatibility

Can the Radius Pivot Video Card coexist in a Macintosh with Apple's Display Card 8/24 GC?

This article has been archived and is no longer updated by Apple.
Radius Tech Support assures us that there should be no problem running a Macintosh system with both cards installed.

For more information, search under: "Radius"

Published Date: Feb 18, 2012

PowerBook Video Mirroring: Screen Anomaly When Scrolling

When using video mirroring on a PowerBook, scrolling through a window may produce video anomalies in some applications.
This article has been archived and is no longer updated by Apple.
Apple has determined that some developers treat video mirroring mode incorrectly causing image distortion, particularly when scrolling.

The application understands that two monitors are connected and copies pixels into each monitor separately. Since the displayed images overlap, the pixels are copied twice and the image gets distorted especially when scrolling.

If you experience this anomaly only in certain applications, contact the developer of the application for a fix.

Developers can reference the following Apple Developer Services information on how to deal with overlapped graphics devices: **http://developer.apple.com/dev/techsupport/develop/issue26/graphicaltruffles.html**.

Power Mac G4: Purpose of Accessory Kit Screws

What are the 4 small screws included in the Power Mac G4 accessory kit used for?
This article has been archived and is no longer updated by Apple.
The four screws included in the accessory kit are used to fasten an additional hard drive to the Power Mac G4 hard drive mounting bracket.

Specific installations can be found in the Installing a Hard Disk or Other Internal Storage Device section in the Setting Up Your Power Mac manual.

Published Date: Feb 18, 2012

MacDFT 1.1: Configuring in NON-SNA Mode

I have a problem configuring MacDFT 1.1 for NON-SNA.

Configuration
MacDFT 1.1
Coax/Twinax NB Card
Cluster Controller 3274 61C - configured for DFT modem to an IBM host

I tried to configure MacDFT 1.1 for NON-SNA. During the startup of MacDFT an error window opened and told me to re-configure MacDFT to SNA-mode because NON-SNA was not a valid configuration. Then I tried to configure MacDFT for SNA and the same error message told me to configure MacDFT to NON-SNA.

Why can't I configure MacDFT 1.1 for NON-SNA?
This article has been archived and is no longer updated by Apple.
It looks like your cluster controller is configured for Bisynchronous communications. If this is the case, MacDFT can provide CUT support only over Bisynchronous, so switching the coax CDEV setting to CUT mode should work.

The significance of the "DFT (NON-SNA)" setting is to support non-SNA channel protocols for locally attached controllers such as the old 41D models. Since your 61C is designed for remote connections, it isn't prepared to handle channel protocols, and MacDFT notifies you of the conflict.

If you're not trying to maintain Bisynchronous communications, and SDLC communications are OK, then you will need to check your controller's customization; if it is set for Bisynchronous, you will need to change it to SDLC in order for MacDFT to provide full DFT capabilities. The attach option is configured in customization question 101 on the "Model/Attach" panel of the customization utility (see the 3174 customization manual for further reference).

iBook: No Networking Services When Booted From CD

When booted from the Mac OS 9 CD, my iBook with 32 MB (megabytes) of RAM (random-access memory) does not see the network. Why is this?
This article has been archived and is no longer updated by Apple.
32 MB is not enough memory for the iBook to run diagnostic and utility applications included on the CD and load the extensions needed for network services. To conserve memory, networking extensions are disabled to free up memory for those utility applications on the CD.

Note: Virtual memory cannot be enabled when the iBook is started from a CD.

When started up from the Mac OS 9 CD you will get an error when opening the AppleTalk control panel, choosing AppleShare in the Chooser, or opening the Network Browser.

If you need to have network access while your iBook is started from CD, start up from the Mac OS 8.6 iBook CD, or upgrade to 64 MB of memory.

AirPort 1.0: About Airport

This article is the About Airport document included with the AirPort software version 1.0.

Note: AirPort 1.2 was released by Apple on 12 June 2000. It is available for downloading from the Apple Software Updates Web site at http://www.apple.com/swupdates/ .

Click the following link to download the English-North American version of AirPort 1.2:
http://asu.info.apple.com/swupdates.nsf/artnum/n11570 .
This article has been archived and is no longer updated by Apple.

About AirPort

Requirements
System Requirements
This version of the AirPort software requires the following:
AirPort capable computer (iBook, iMac, or Power Mac G4) with an internal AirPort Card installed.
Mac OS 8.6 or greater.

Notes about using the AirPort software

Reconnecting to networks after wake from sleep

Remote servers mounted on your computer's desktop will not reappear after waking from sleep if the connection is made using AirPort.

Using BootP

The current version of the AirPort software only supports obtaining an IP address through a fixed IP address or using DHCP. Do not set your TCP/IP control panel to BootP when using AirPort. Setting TCP/IP to BootP may cause unexpected results.

Notes about the AirPort application and Control Strip portion

Switching networks

Switching wireless networks will interrupt any network services currently in progress. For example, if you switch networks while transferring a file, the file transfer process will be interrupted.

You may also notice a slight delay when switching between wireless networks.

Display of AirPort networks

In the AirPort application and the AirPort Control Strip module, AirPort networks are displayed in order of the network signal strength.

Disconnecting the AirPort Base Station

The manual that comes with the AirPort Base Station incorrectly states that you can disconnect the AirPort Base Station from the Control Strip. The only way to manually disconnect the AirPort Base Station is to use the AirPort application.

Notes about Internet access

Setting up an AirPort Base Station for Internet access

To use AirPort to access the Internet, you must have an Internet account with an Internet service provider (ISP). In addition, you need to have a traditional way to access the Internet, either through a phone line, cable, or DSL modem. Before using the AirPort Setup Assistant, make sure that the Internet connection on the computer that you are going to use to configure the base station is functioning properly. As part of the setup process the assistant will transfer your existing Internet settings from your computer to the AirPort Base Station.

Obtaining an Internet account

You cannot use the AirPort Setup Assistant to obtain an Internet account. Because the AirPort Setup Assistant uses your computers existing Internet settings to configure an AirPort Base Station, you must already have an Internet account. If you have not set up your computer to access the Internet, open the Assistants folder on your hard disk and double-click the Internet Setup Assistant.

Connecting to the Internet

When connecting to the Internet using the AirPort Base Station, you may notice that the initial request for a web page fails. This is because the AirPort Base Station has not completed the dial up process with your ISP. If you notice that the first connection fails, wait a few minutes until the base station completes its connection with your ISP.

Internet Service Provider (ISP) Compatibility

The following ISPs are not compatible with the current version of the AirPort software

CompuServe
America Online

For more information on ISP compatibility see the Apple Support Web Site at www.apple.com/support.

ISPs that use DNS addressing

The AirPort Base Station is not compatible with ISPs that use server assigned DNS addressing.

ISPs that provide IP addresses using DHCP

Due to differences in the ways that IP addresses are provided using DHCP you may encounter problems using your AirPort Base Station. If you are unable to use the AirPort Base Station and find that it has an IP address of "00.000.00.0" in the AirPort Utility, contact your ISP and ask to get a static IP address assigned to your account.

Notes about the AirPort Utility

Configuring an AirPort Base Station

The AirPort Utility is designed for advanced base station configuration. Most users will be able to configure all of the necessary base station settings using the AirPort Setup Assistant.

Configuring a third party base station

The AirPort Utility cannot be used to configure a non-AirPort Base Station.

Notes about base stations

Monitoring the AirPort Base Station Modem Status

Your AirPort software only provides "connected" or "disconnected" status information for the modem. If you want to monitor additional status information for the modem in order to troubleshoot a problem you can use one of the following programs.

Syslogd 2.1.3 available at http://www.classicalguitar.net/brian/apps/syslogd/

MacNetLogger 0.96b8 available at http://www.laffeycomputer.com/netlogger.html

Using Multiple AirPort Base Stations on the Same Network

You can connect multiple AirPort Base Stations to the same Ethernet network. However, each base station should have a unique network name. For example, if you wanted to connect several base stations to a network in a school, you could place a base station in each building. Then the user would see the following as available networks:

Science building wireless network
History building wireless network
Language building wireless network

The AirPort Base Station cannot be used to extend the size of an existing network.

IMPORTANT If you have multiple AirPort Base Stations on your network and one of them is using DHCP to assign IP addresses, do not set the other base stations to obtain their IP addresses from DHCP.

Resetting your AirPort Base Station password

The manual that came with your AirPort Base Station incorrectly states the process for resetting your AirPort Base Station password. If you forget the password to your base station or network, you will need to do a forced reload of the AirPort Base Station firmware. See the Reloading Base Station Firmware read me file located in the Base Station Extras folder on your AirPort CD for more information.

Notes about an AirPort Software Base Station

Using a computer as an AirPort software base station

In the documentation that came with your AirPort Card or new computer, you may find a reference to setting up your computer as a base station (also known as a software base station). This feature is not available in the current version of the AirPort software.

Notes about using non-AirPort equipped computers

Connecting non-AirPort equipped computers to an AirPort Base Station

You can attach a computer with Ethernet to an AirPort Base Station. If you want that computer to share the single Internet connection provided by the base station you will need to use the AirPort utility to turn on DHCP on the Ethernet portion of the network.

IMPORTANT You should not turn DHCP on the Ethernet portion of your network if you are on a larger network where there is a possibility that a DHCP server already exists or if you are using a cable or DSL modem. For more information contact your system administrator or Internet service provider.

To turn on DHCP for the Ethernet portion of your network do the following:

1. Open the AirPort Utility
2. Select your base station
3. Click the Internet tab
4. Make sure that the "Use DHCP to also provide IP addresses on Ethernet" checkbox is selected.

For additional information on configuring non-AirPort equipped computers see the documentation that came with your base station or look in the wireless Internet and networking section of Mac Help, available from the Help menu.

Notes about compatibility

Communication programs that use terminal windows

Communication programs that use terminal windows for login are not supported by the current version of the AirPort software.

Applications not compatible with network address translation (NAT)

The following applications are not compatible with NAT (the process used by the AirPort Base Station to share a single IP address.)

StarCraft
ICQ
Retrospect Remote
DAVE

For more information on application compatibility see the Apple Support Web Site at http://www.apple.com/support. For information on NAT see Mac Help (available from the Help menu).

Easel-Type Programs are Available for Macintosh

I need to find out about a product called Easel, currently available for MS-DOS systems. Is there anything equivalent for the Macintosh?

This article has been archived and is no longer updated by Apple.
Easel is a front-end package that allows you to build a better interface to what may perhaps, from a GUI standpoint, be a more complex or inelegant system interface.

Proven programs for the Macintosh that perform similar functions include HyperCard and MitemView.

For more information, search under: "MITEM"

About the NetBoot Image Pieces Package

This article describes the NetBoot Image Pieces package included in the installers of the iMac (Summer 2000), Power Mac G4 (Gigabit Ethernet), and Power Mac G4 Cube computers.
This article has been archived and is no longer updated by Apple.
The NetBoot Image Pieces is for use with NetBoot clients that have internal Zip drives, such as the Power Macintosh G3 or Power Mac G4 computers. When updating the NetBoot image to work with these computers, be sure to select and install this package.

If you do not install this software, your other NetBoot clients will still start up from the NetBoot server, but they may not have software to access their Zip drives.

The pieces installed by NetBoot Image Pieces are:

Macintosh: 24-bit Image Copying Problem Caused By Heap Space

I'm having trouble copying and pasting between Microsoft PowerPoint and Solutions International's SmartScrap. I tried to copy several 24-bit images from the PowerPoint document (they occupy a total of about 2.5MB), but when I tried to paste them, the first couple pasted OK but the rest didn't, and the machine hung.

This article has been archived and is no longer updated by Apple.
We solved the problem by increasing the system heap space.

Normally the system has a small amount of heap space available. We increased the space using CE Software's Heapfixer, and all the problems went away.

We also checked with both Solutions International and Microsoft, and neither was aware of any other conflicts.

Microsoft, however, strongly recommends that anyone using 24-bit graphics in PowerPoint upgrade to version 2.0.1d.

For more information, search under: "CE Software"

PowerBook (FireWire): Expansion Bay Device Compatibility

This article provides expansion bay device compatibility information for the PowerBook (FireWire) and previous PowerBook G3 computers. This article has been archived and is no longer updated by Apple.

DVD Drives

The DVD expansion bay device that ships with the PowerBook (FireWire) does not work with any previous PowerBook G3 Series model. The previous model DVD module does not work with the PowerBook (FireWire).

Battery

The PowerBook (FireWire) uses a battery similar to the PowerBook G3 Series (Bronze Keyboard). The two batteries are interchangeable between these two computers only.

Other expansion Bay Devices

Expansion bay modules for the PowerBook G3 Series (Bronze keyboard) will function properly in a PowerBook (FireWire). It is possible that some third party expansion bay devices made for the PowerBook (FireWire) will not work with older PowerBook models. You should consult with the third party vendor before purchasing if this is of concern.

PowerBook (FireWire) and G4: Connecting Non-USB or Non-FireWire Peripherals

This article provides direction on how to connect SCSI, ADB, and mini-DIN 8 serial peripherals to the PowerBook (FireWire) and PowerBook G4.
This article has been archived and is no longer updated by Apple.
There are a multitude of adapters available that will enable older peripherals that relied on SCSI, ADB, or serial ports to be connected to the PowerBook (FireWire) and PowerBook G4.

For more specific information, search the Apple Products Web page at http://www.apple.com/products. Or, visit the Macintosh Products Guide at http://guide.apple.com .

Macintosh Display Card 8/24: NTSC Video Encoding

I am very interested in getting a decent video signal from Macintosh II systems. I'm interested in Apple's Display Card 8*24 because of the convolution filter that (as far as I know) has no equivalent in third-party products.

Will the Display Card 8*24 ship with a CDEV like the Macintosh II video card utility to step the board down to interlaced NTSC scan rates? If not, how can I get such a utility/application?

Currently, I'm using a Truevision VIDI/O box to do the RGB encoding. Has anyone tried the Truevision product with the Display Card 8/24?

This article has been archived and is no longer updated by Apple.
The Display Cards 8*24 and 8*24 GC do not use software for switching to the NTSC interlaced mode. To put the Display Card 8*24 GC into the NTSC mode, a properly configured cable is all that is required. For more information, search under "NTSC output without converter".

To acquire a color NTSC signal from any Apple Macintosh display card, an RGB-to-NTSC converter will be required.

RasterOps and Truevision both have RGB-to-NTSC converters. RasterOps' Video Expander and Truevision's VIDI/O Box accept the RS-170-A output of the Display Card 8/24 and 8/24 GC and generate a full color NTSC interlaced video signal. Both of these interface boxes also provide S-Video (also known as Y/C component video) output via the standard 4-pin mini-DIN connector. S-Video connections are used by S-VHS, HiBand 8mm, and ED Beta video devices.

Another device for RGB-to-NTSC conversion is ComputerVideo's Video NTSC Encoder. This was designed for the older Macintosh video card; however, it should work with the new display cards when the correct cable is used (see above).

For cable requirements for these interface devices, please check with the appropriate interface manufacturer.

For 8-bit video, Apple's convolution provides one of the finest methods for eliminating the single-pixel flicker that NTSC produces. When using 24-bit color, a different approach is required to address the NTSC flicker issue, since Apple convolution works only to the 8-bit level. Scan converters, like RGB/Videolink 600A, have been used for many years in the professional computer graphics companies to address NTSC flicker.

Scan converters would be used for television broadcast-quality 24-bit images. Scan converters not only convert the RGB signal to NTSC, they also eliminate the flicker associated with horizontal single-pixel lines and provide aspect-ratio conversion, color-bar generation, video transitions, freeze frame, and video mixing.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Mac OS X Server 1.2v3: Starting Up on a Power Mac G4 (Gigabit Ethernet) With ADC Display

This article provides instruction on getting Mac OS X Server 1.2v3 to start up on a Power Mac G4 (Gigabit Ethernet) computer when an Apple Display Connector style display, such as the Apple Cinema Display (ADC) or the Apple Studio Display LCD (ADC), is used.
This article has been archived and is no longer updated by Apple.

Symptom

The computer fails to respond or "freezes" at the "Starting Mac OS X Server" screen, before the progress bar is drawn. If starting up the computer in verbose mode, the system fails to respond after init posts a message about an unrecognized option.

Solution

1. Make sure the keyboard is connected to USB port 1 on the back of the computer
2. Connect the mouse to the keyboard.

For all versions of Mac OS X Server, the mouse must be daisy-chained to the keyboard which must be connected directly to the computer.

Either USB port can be used if using the VGA video connector.

Display Card 8/24: RS-170 External Sync

Do the Apple Display Cards 8/24 and 8/24 GC accept an external sync signal when in RS-170 mode? How is RS-170 external sync mode enabled?

This article has been archived and is no longer updated by Apple.
The video cards alone do not except external sync -- however, if the video cards are being used in an environment where external sync is an issue, an RGB-to-NTSC converter is very likely in use. Truevision's VIDI/O Box and RasterOps' Video Expander can be used with either video card to allow external sync ability.

The specifics of using external sync are provided in each converter manufacturer's documentation.

At announcement, many references were made to the Display Card 8/24 being RS-170. In actuality, the production video cards meet the full RS-170-A specifications -- RS-170 being the original black and white specification; RS-170-A is the color extension to the original specification.

Without one of the above converters, the interlaced signal coming from the Display Card 8/24 and 8/24 GC will still be in black and white. With one of the converters, the Display Card 8/24 and 8/24 GC will provide full RS-170-A color.

Macintosh: "Rounding Errors"

I'm having trouble doing a simple math calculation with FileMaker II. All subsequent programs I tried produced the same mathematical "error" (Excel and the Calculator desk accessory are a couple).

The calculation is very simple: 1194.6 - 500 - 640 - 54.6 = X

The result should be 0; however, all software produced the result -2.428612866E-17.

I can cure this problem in FileMaker II by rounding the result to two decimal places, but I am very interested in why the result does not go to zero. My IBM PC produced the same result. I gather the answer lies in the way personal computers handle subtraction.

This article has been archived and is no longer updated by Apple.
The rounding errors you have run into on the Macintosh and IBM PC have been around since the beginning of personal computers (and longer!).

Computers must convert from a floating point decimal number to binary in order for the CPU to do math operations. To make the conversion process perform at a user-tolerable rate, past computer designers came up with "short cut" processes to do the conversion. These short cuts cause slight rounding errors.

In the example you describe, the error is .00000000000000002486.... This can be annoying, but is a good trade-off for the amount of time that is saved when doing math functions.

Apple Hardware Test 1.0: PowerBook Read Me

This article comprises the PowerBook Read Me for Apple Hardware Test 1.0.

This article has been archived and is no longer updated by Apple.

About Apple Hardware Test

To use the Apple Hardware Test CD, restart your computer while holding down the C key until the "Loading..." icon appears, then you may release the C key. Loading will take approximately 45 seconds. Apple Hardware Test's main screen will appear. Follow the on-screen instructions and recommendations.

Apple Hardware Test is a diagnostic tool for detecting issues with your computer's internal hardware components such as the logic board, memory, modem, video RAM, and Apple's AirPort card. It does not check externally connected hardware components such as USB drives or FireWire devices; it does not check non-Apple devices such as PCI cards from other vendors.

Apple Hardware Test does not check your computer for issues with the Operating System (OS) or other software related issues such as application or extension conflicts.

Apple Hardware Test for PowerBook version 1.0 is distributed only with the Apple PowerBook (with FireWire), and will not work with any other computer. References to AppleCare recommendations are intended for U.S. customers only. Future versions of Apple Hardware Test may be distributed for other Apple products and for use in locations outside of the United States.

If you suspect your computer has a hardware issue, the information provided by Apple Hardware Test can help identify the issue. If Apple Hardware Test detects a failure, an error code will be displayed. Please make a note of the error code before pursuing support options. If no hardware failure is detected, the issue may be software related.

Known issues

Apple Hardware Test cannot be used with an external input device (such as a mouse) attached directly to the USB port on the PowerBook (with FireWire). Please disconnect the external device, and use the integrated track pad to move the cursor while running Apple Hardware Test.

AppleCare Recommendations

Apple Hardware Test is one of several tools and procedures you can use when your Macintosh is having trouble. Here are some steps you can follow to help resolve issues. Please back up your data before performing any of these steps.

1. Turn the computer off and on.
You can often eliminate issues by shutting down and restarting your system.

2. Check cables, peripherals, and user controls.
Shut down your computer. Then disconnect and reconnect all cables. Disconnect all peripherals (such as printers, scanners, cameras and external mass storage devices) to see if they are causing conflicts with your system. Adjust user controls on your monitors and other peripherals to see if this helps.

3. Turn off system extensions.
Restart your system while holding down the Shift key until the following message appears: "Extensions disabled." Then release the key. This turns off system extensions that often cause conflicts. If this solves your issue, use the Extensions Manager to turn off extensions that may be causing the issue.

4. Rebuild the desktop.
Restart your system while holding down the Option and Command keys. Click OK when asked if you want to rebuild the desktop.

5. Start up from the system CD that shipped with your computer.
Start your system from the system CD by holding down the C key until you see the smiling Mac face. If the system works properly when started (booted) from the system CD, you can generally assume that the issue relates to the software which is installed on your computer.

6. Start up from the Apple Hardware Test CD, and run the Quick and Extended Tests.
If the system does not work properly when started (booted) from a known-good system CD (Step 5), you can generally assume that the issue relates to your computer's hardware components. The Apple Hardware Test CD can often be used to start up your computer even if it will not boot into the Mac OS. If Apple Hardware Test passes both the Quick Test and the Extended Test, the issue may be software related. If Apple Hardware Test fails, make a note of the error code and contact Apple (Step 10).

7. If you are an Apple Protection Plan customer, run TechTool Deluxe from Micromat, provided with the Protection Plan.
This diagnostic tool can help identify and repair issues with your system, such as hard disk corruption. Please read the user manual on the CD for

more information.

8. Re-install Mac OS.
In many cases, a clean installation of the Mac OS will fix recurring issues. Please follow the instructions in your user manual or on your Restore CD to reinstall the Mac OS. Back up any data before reinstalling.

9. Refer to online help and the Internet for assistance.
The Mac OS help system under the Help menu in the Finder includes a wealth of technical information. Apple's Knowledge Base, Apple Discussions, and other resources for technical help and support are available 24 hours a day at http://www.apple.com/support/protection .

10. Call the Apple Service and Support line for assistance.
If these steps don't help resolve the issue, please call the following number for more assistance. In the United States 800-500-7078 seven days a week (excluding holidays) 6 a.m. to 6 p.m. PST. Telephone hours may vary. Apple reserves the right to change telephone hours at any time.

Final Cut Pro 1.2.1: Audio Blast at End of Video Clip

There is an issue that occurs when capturing clips with Final Cut Pro 1.2.1 and Mac OS 8.6 with QuickTime 4.1 (or later). After capture, there will be an audio blast at the end of the captured clip. This article describes how to resolve this behavior.
This article has been archived and is no longer updated by Apple.
When capturing clips with Final Cut Pro 1.2.1 and Mac OS 8.6 with QuickTime 4.1 (or later), an audio blast will occur at the end of the clip. To resolve this behavior, use one of these two possible workarounds:

- Preferably, upgrade to Mac OS 9.0 or later (Final Cut Pro 1.2.5 will require Mac OS 9.0 or later)
- If this is not possible, install QuickTime 4.0.3 available at http://www.apple.com/quicktime/download/support/68k/

Note: In order to install QuickTime 4.0.3 over QuickTime 4.1 or later, you must follow these steps:

1. Remove all QuickTime extensions and control panels from their respective folders.
2. Restart the computer.
3. After restarting, install QuickTime 4.0.3.

Published Date: Feb 18, 2012

Final Cut Pro: Allocating Memory

The amount of memory allocated to Final Cut Pro can make a big difference in performance. This article discusses how much memory should be allocated, as well as how to do it.
This article has been archived and is no longer updated by Apple.
While the minimum system requirements for Final Cut Pro specify 128MB of RAM, serious users are advised to have at least 256MB of RAM installed in their machine. While Final Cut Pro will run with the default 65MB of RAM allocated to it, it is preferable to have anywhere from 80 to 150MB of RAM allocated exclusively to Final Cut Pro. A larger RAM allocation will allow higher performance for longer projects, as well as for those with numerous layers.

To allocate more memory to Final Cut Pro, users should first know how much free memory they have available to them. Follow the steps below:

1. Quit out of Final Cut Pro

2. From the Finder, with no other applications running, go to the Apple menu and select "About this Computer"

3. In the resulting dialog box, note the "Largest Unused Block" in megabytes. This is the total amount of memory not used by the System, and is the most you can possibly allocate to Final Cut Pro. Note: It is not prudent to allocate all of your free memory to Final Cut Pro. Instead, subtract 15 from this total, and write this number down as your maximum memory allocation.

4. Close this window

5. Now, select the Final Cut Pro application icon

6. In the File menu, select Get Info>Memory

Figure 1 Memory Sub-menu

7. In the resulting dialog box, set the Preferred Size to be at least 80MB, preferably closer to 150MB if you have this much RAM free (especially important for longer projects)

Figure 2 The Memory Info Box for Final Cut Pro. Note that Virtual Memory is Disabled.

8. Optionally: Users may also set the Minimum Size to match the Preferred Size. This will insure that Final Cut Pro allocates all the memory you've specified every time it launches. If memory is not available, a warning will be issued and Final Cut Pro won't launch. In this case, users may either quit out of other currently running applications, or allocate less memory to Final Cut Pro in both Minimum and Preferred boxes.

Doing this will make sure that Final Cut Pro always has the amount of memory allocated that you expect it to, even in cases where users have multiple applications running simultaneously.

Figure 3 Changing Minimum Size last

Resolving poor image quality in DV QuickTime movies

QuickTime movies imported into Final Cut Pro, Final Cut Pro HD, and Final Cut Express with the DV codec and played with another QuickTime aware application may appear to be of lower resolution. Learn how to force QuickTime to display DV movie clips at their highest resolution.
This article has been archived and is no longer updated by Apple.
When DV QuickTime files are opened with either the QuickTime Player or some other QuickTime aware application, the opened DV movie may look as if it is jagged or at low resolution. This is not an indication that something is wrong with your DV movie.

When DV movies are rendered or imported, they are created with a default High Quality setting turned off. This setting allows these movies to be played back at higher framerates with no additional decompression hardware by lowering the apparent video quality displayed by the monitor. This is only a display setting. The full resolution of the video track remains untouched, and can in fact be toggled to display the movie's full resolution, although playback with the High Quality setting turned on will result in dropped frames.

This setting can be accessed by anyone with QuickTime Pro (users of Final Cut Pro already have this license, others may purchase one at the QuickTime web site). With your clip open in the QuickTime player:

1. From the **Movie** menu, choose **Get Movie Properties** (the clip we use in this example is called "Outside 001")

2. In the resulting dialog box, from the left-hand pop-up menu, choose **Video Track** and then from the right-hand pop-up, choose **Quality**.

3. Select the High Quality Enabled check-box to enable or disable this setting

   As you toggle back and forth, notice how the movie goes from jagged to sharp.

   If you leave High Quality toggled on, you may be asked if you want to save this clip when either closing it or quitting out of the QuickTime Player. Saving at this time will only preserve this setting internally to the file, and will not do anything to change the video track itself.

Published Date: Feb 18, 2012

Final Cut Pro: Explanation of "Servo Can‘t Lock" Error message

The Servo Can't Lock message indicates that the tape transport mechanism in the video tape recorder is not able to sync up as Final Cut Pro expected. This article covers the two most common causes of this, and how to eliminate them.
This article has been archived and is no longer updated by Apple.
The two most common sources of the Servo Can't Lock message are:

1. The tape transport of your VTR requires more time to sync up to where the computer thinks it is. Try increasing the Pre-Roll time in the Device Control Preferences tab.

Figure 1 The Pre-roll field of the Device Control tab

2. If you are using Firewire, try switching over to Firewire Basic, also in the Device Control Preferences tab.

Figure 2 Switching to the Apple Firewire Basic protocol in the Device Control tab

You may consult the Final Cut Pro Device Qualification page for more information on interoperability with your particular video device at http://www.apple.com/finalcutpro/techspecs/qualification.html

Installer Software: Where to Find Documentation

I'm interested in creating an install program (perhaps in C or Pascal) that will automatically install software and utilities on Macintosh systems.

Is there an easy way to write installer scripts for applications? It is becoming more time-consuming, as my Macintosh network has expanded, to update software on every machine.

Is there a way to produce installer scripts similar to what Apple offers with the operating system software -- without getting into Macintosh programming?

This article has been archived and is no longer updated by Apple.

You can use Apple's Installer software. Documentation on the software and its scripts is available on the Developer web site. Use the following path to find it:

Developer Support
Developer Services
Tool Chest
Developer Utilities
Installer 3.4
Installer.sit (StuffIt)

Published Date: Feb 18, 2012

Final Cut Pro 1.2.5: ProMax DV Toolkit Interferes With New Apple DV Codec

Final Cut Pro 1.2.5 has new YUV rendering capabilities that, along with the Apple DV codec, supersede the use of the DV codec that comes with the Promax DV Toolkit. Despite this, having both installed on the same computer disables this new feature. This article describes how to resolve this issue by uninstalling the Promax DV Toolkit.

This article has been archived and is no longer updated by Apple.

If you have the Promax DV Toolkit 3.0 installed, the option to render in YUV when using Final Cut Pro 1.2.5 is not available. Even if the Promax codec is not in use in favor of the Apple DV codec, the "Always Render in RGB" checkbox is checked and dimmed as long as the Promax codec remains installed.

The solution is to remove all of the DV ToolKit extensions. The uninstaller does not do this, so you must remove them individually by dragging the necessary files to the Trash.

Published Date: Feb 18, 2012

Final Cut Pro 1.2.5: PAL Digital Hi-8 Camcorders Recognized as NTSC

This article describes an issue that arises when using PAL Digital-8 cameras with analog Hi-8 tapes, FireWire and Final Cut Pro 1.2.5
This article has been archived and is no longer updated by Apple.
Digital-8 camcorders are capable of playing back from both Digital-8 and analog Hi-8 videocassettes. If you connect to a PAL Digital-8 camcorder via FireWire when a Hi-8 tape is inserted, you will find that the camcorder is inappropriately recognized as NTSC instead of PAL.

As a result, a PAL setting will not show up in the Source popup, accessed by the Video button in the Capture Preferences tab.

To avoid this situation, use Digital-8 tapes instead.

Published Date: Feb 18, 2012

PrintMonitor: LaserWriter Timeout Messages

If a few users are on the same network sharing a LaserWriter and one of them has sent a print job of many (say 100) pages to the LaserWriter, then the others have to wait for that job to be finished to capture the LaserWriter for their print job.

If they work under MultiFinder, and background printing has been activated in the Chooser, during the large print job, the print jobs of others will be spooled to their local disks without being canceled because of a timeout error.

Perhaps you can tell me if PrintMonitor has its own timeout mechanism and if so, is it possible to alter the timeout values by patching some code/resource?

This article has been archived and is no longer updated by Apple.
PrintMonitor returns the message in question after the LaserWriter returns a timeout error. We occupied a system for over two hours, and, after releasing it, PrintMonitor printed the file that had been spooled.

If you are seeing excessive timeout errors, we suggest changing the timeout limits. To do this, see the Tech Info Library article, "LaserWriter: How to Change the Manual Timeout".

Published Date: Feb 18, 2012

RMS and DATATRIEVE: Macintosh File Access

Are you aware of a product for the Macintosh that allows direct access to RMS flat files? I am looking for programs that also support DATATRIEVE.

Also, is DATATRIEVE -- which was supported under CDD (Common Data Dictionary) -- supported under CDD+?

This article has been archived and is no longer updated by Apple.

1) We are not aware of a product for the Macintosh that provides an interface to a flat file system such as RMS. Although the capability does exist in the Data Access Language (formerly CL/1) architecture, it would require development efforts on the host, since no such host services have been developed to our knowledge.

   One option would be to develop your own environment on the host using MacWorkStation. Since the interface to the RMS file system is provided through VMS run time libraries, you could write a MacWorkStation application that accessed those libraries and presented them on the Macintosh. However, this would restrict the presentation on the Macintosh to MacWorkStation, and you would have to use Copy and Paste to transfer the information to other applications.

2) We are not aware of any product for the Macintosh that supports VAX DATATRIEVE. Please note the VAX DATATRIEVE is a query and report system and is a uniform access method for data stored by RMS, VAX Rdb, and VAX DBMS files; it does not have its own file architecture. Programmable softkeys such as ones provided by PacerLink can be used to program DATATRIEVE commands. If you are looking for products to access RMS files, then the answer is the same as in (1) above.

3) According to DEC's Pre-purchase Technical Assistance, VAX DATATRIEVE version 5.0 will work with VAX Common Data Dictionary/Plus (VAX CDD/Plus version 4.2) and VAX CDD as long as you run VAX/VMS 5.2 or 5.3.

Apple II: Transferring Data to the Macintosh

Can the Apple 5.25 PC Drive (and card) read ProDOS 5.25-inch disks under AFE?

This article has been archived and is no longer updated by Apple.
Apple 5.25 PC Drive only supports disks that are formatted using the MFM encoding methods. Therefore, it does not read ProDOS-formatted disks, which use GCR. Alternative ways to move data from the Apple II to the Macintosh include AppleShare, a serial link (cable and/or modem), and by first moving the ProDOS data to 3.5-inch disks, which any Macintosh will mount.

You may find the AFE Works-Works translator helpful when actually translating the files. It is on the InfoSource CD-ROM available from Apple.

Power Mac G4 Cube: Correct Position for Adequate Cooling

This article explains how to position the Power Mac G4 Cube computer so that is adequately cooled during normal use.
This article has been archived and is no longer updated by Apple.
The Power Mac G4 Cube computer does not have a cooling fan. Heat generated by the computer--a normal part of its operation-- escapes through cooling vents. To provide adequate cooling for the computer's internal components, it must be positioned vertically with the DVD disc drive facing up.

Do not place anything on top of the computer that would prevent its normal ventilation.

Power Mac G4 Cube: Delay Before Startup Sound is Heard

When you start up a Power Mac G4 Cube computer there is a slight delay before the startup sound is heard through the Apple USB Speakers.
This article has been archived and is no longer updated by Apple.
When you start up a Power Mac G4 Cube computer there is a delay of approximately five to seven seconds before the startup sound is heard through the Apple USB Speakers. This is normal. The Power Mac G4 Cube computer does not have an internal speaker, so the startup sound is routed through the Universal Serial Bus (USB) whose drivers are not available until after the computer is turned on.

If no speakers are connected to a USB port, only the power light indicates that the computer has been turned on.

Business BASIC III: Print Using

This article has been archived and is no longer updated by Apple.
The string specification in Print Using takes only as many characters of a long string as are required to fill its field length; hence, the rest of the string is ignored. This example:

```
A$ = "abcdefghijklmnopqrstuvwxyz"
Print Using "3X,10A,3X";A$
```

returns:
abcdefghij

A$ is truncated to 10 characters. Use the MID$ function to split up a string into multiple lines.

PostScript Fonts: How to Determine ASCII Assignments

Users with typesetting equipment and LaserWriters have run into the problem that the fonts generated by the LaserWriter are not quite the same as those from the typesetter being used. This is causing some problems when documents are printed on machines other than the LaserWriter.

This article describes a method for determining the ASCII assignment of any font.
This article has been archived and is no longer updated by Apple.
By sending a PostScript program (listed below) to a LaserWriter, a user can determine which character is encoded to what ASCII assignment for any laser font. For example, this specific program gives all ASCII codes and their respective characters for the Times-Roman font. By changing the name of the font, where noted with the % and comment, the ASCII assignment and character can be determined for any laser font.

```
/Times-Roman findfont
[12 0 0 -12 0 0] makefont setfont
60 47 moveto
(ASCII Code - Character Times-Roman) show %Change the font name
here.
60 59 moveto
500 59 lineto
500 762 lineto
60 762 lineto
60 59 lineto
stroke
/Times-Roman findfont %Also, change the font name
here.
[12 0 0 -12 0 0] makefont setfont
/char 1 string def
/nstr 3 string def /newline
{ currentpoint 14 add
exch pop LM
exch moveto } def
/prt-n
{nstr cvs show} def
/prtchar
{ char 0
3 -1 roll put
char show } def
/PrintCodeandChar
{ dup prt-n
( - ) show
prtchar newline } def
/LM 72 def
LM 72 moveto
0 1 49 {PrintCodeandChar} for
/LM 144 def
LM 72 moveto
50 1 99 {PrintCodeandChar} for
/LM 216 def
LM 72 moveto
100 1 149 {PrintCodeandChar} for
/LM 288 def
LM 72 moveto
150 1 199 {PrintCodeandChar} for
/LM 360 def
LM 72 moveto
200 1 249 {PrintCodeandChar} for
/LM 432 def
LM 72 moveto
250 1 255 {PrintCodeandChar} for
showpage
```

This PostScript program can be sent to the LaserWriter with the LaserWriter Utility that can be located on the LaserWriter Utility Disk. Put the text of this program into a text file (you can use TeachText) and send it to the printer with the LaserWriter Utility.

For additional information on PostScript, refer to the Adobe PostScript Language Reference Manual, 2nd Edition, by Adobe Systems, Inc.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Power Mac G4: Overview of Multiprocessing

This article describes the type of multiprocessing operating mode used by the Power Mac G4 (Gigabit Ethernet).
This article has been archived and is no longer updated by Apple.
Multiprocessing refers to the function of a computer using more than one processor to perform a computing task. The Power Mac G4 (Gigabit Ethernet) uses symmetric multiprocessing.

Symmetric multiprocessing means the workload of the overall system can be spread equally among the processors available in the computer. Any processor can do any task. The operating system has to be specifically designed to take advantage of multiple processors but the applications do not need to be. However, applications that are written to take advantage of them will experience a performance increase.

AppleShare for Windows: Installing Unsupported Network Card

Although no longer distributed by Apple, this article provides information on configuring an unsupported network interface card with AppleShare for Windows.
This article has been archived and is no longer updated by Apple.
If you are using Windows for Workgroups Windows 3.11 or Windows 3.1 without Windows networking software, and you have an a vendor-supplied ODI driver for your unlisted network adapter, you may be able to use the procedures in this section to install AppleShare Client for Windows.

WARNING: Installing your system for networking requires that you manually install the network adapter driver and edit your driver configuration file and your DOS startup batch files. Performing these procedures incorrectly can cause your computer to fail.

Before performing the following procedures, you should locate the software and documentation that came with your network adapter. As you perform the procedures, you will need information from the documentation.

1. If your network adapter is not already installed, install and test it, following the instructions in your network adapter documentation.

2. Restart your computer and run Windows.

3. Run the INSTALL.EXE program on the AppleShare Client for Windows Disk 1.

4. In the Installation Options dialog box, choose the Standard Installation option and click Continue. The Select Adapter dialog box appears.

5. Select the line at the end of the adapter list that reads "[Other] Unlisted Adapter Option," and click OK. The Network Adapter Settings dialog box appears.

6. Enter the configuration settings for your network adapter. If possible, select values that match the adapter configuration settings you used in completing step 1 above. If no matching settings are displayed, simply continue with step 7. If you are already running ODI-based networking software, AppleShare Client for Windows Installer will use your existing network adapter configuration settings.

7. Complete the AppleShare Client for Windows installation.

8. Exit Windows and estart your computer as instructed by the Installer. If your computer was not already running ODI-based networking software, continue with step 11.

9. If your computer was already running ODI-based networking software using your network adapter card, edit the file ATDRIVER.BAT (in the C:\\APPLE\\A_SHARE directory by default). Remove the word "REM" from the beginning of the last line so that it reads "C:\\APPLE\\A_SHARE\\ODI.EXE".

10. Restart your computer. AppleShare Client for Windows is completely installed and should run when you start Windows. Skip the rest of this procedure.

11. Use DOS to copy the ODI driver and any supporting files for your network adapter to your AppleShare Client for Windows directory. The default directory path is C:\\APPLE\\A_SHARE.

Note: Since Novell developed the ODI arcitecture, the ODI driver found on the installation disk will often be in a "Novell" or "NetWare" directory. And the actual driver may be referred to as "NetWare driver".

12. Edit the NET.CFG file in the C:\\APPLE\\A_SHARE directory. First, replace all strings of four consecutive X characters (that is, XXXX) with the file name of your driver, excluding the .COM extension for the file. Next, change any parameters that do not match your adapter configuration settings.

Check the values for the following parameters:
- the interrupt request level, a one- or two-digit number preceded by INT #1
- the I/O port number, a 3-digit value such as 300, preceded by PORT #1
- the direct memory access channel, a value of 1 or 2 preceded by DMA
- the memory access address, a data address value such as D8000, preceded by MEM You should consult your network adapter card documentation to determine if other parameters are required for your system.
Finally, save the NET.CFG file.

13. Edit the file ATDRIVER.BAT (in the C:\\APPLE\\A_SHARE directory by default). First, remove the word "REM" from the beginning of every line. Next, replace the string "XXXX" in the second line of the file with the filename of your network adapter driver. Be sure to include the filename extension.

14. Save the ATDRIVER.BAT file.

15. Restart your computer by turning it off.and on. AppleShare Client for Windows is completely installed and should run when you start Windows. If you experience any problems after completing these instructions, see the file C:\\APPLE\\A_SHARE\\PROBLEMS.WRI.

Published Date: Feb 18, 2012

Installing AppleShare Client for Windows

This article is a guide to installing AppleShare Client for Windows with other network software such as Novell Netware and Microsoft Windows for Workgroups.
This article has been archived and is no longer updated by Apple.

Novell NetWare

ODI ARCHITECTURE

ODI (Open Datalink Interface)

Novell and Apple co-developed the ODI architecture. The ODI architecture refers to a series of network drivers loaded in DOS and the order in which they are loaded. ODI was developed in order to be able to use any vendor's network card with NetWare by simply installing the MLID driver provided by the vendor. NetWare, Novell's primary product, running its native IPX protocol, loads 4 drivers into memory:

LSL.COM-Link Support Layer

This driver loads first. It provides an interface between network hardware and network software. LSL.COM, along with its configuration file (NET.CFG) tell the network card driver what type of network is being used and also includes settings such as IRQ, memory address, buffers, and others.

XXXX.COM-MLID (Multi Link Interface Driver)

The name of this driver is specific to the type of network card being used, but always contains the .COM file extension. For example, if an NE2000 ethernet card is being used, the driver is called NE2000.COM. This driver relies on the LSL.COM for its configuration.

IPXODI.COM-Protocol driver

This is a driver which only NetWare uses. It is a protocol driver for the IPX protocol

VLM.EXE-Virtual Loadable Module

Provides network services such as file and print capabilities in a NetWare environment.

NetWare 3.11 vs 3.12

NetWare 3.11 and earlier used a driver called NETX.EXE instead of the current VLM.EXE which is used with 3.12 and later. When working with NetWare, it is important to determine if NETX or VLM is being used. 3.12 is backward compatible with NETX, meaning that NETX.EXE can be substituted for the VLM.EXE in version 3,12 and later.

NETWARE USING NETX (3.11)
LSL.COM
XXXX.COM
IPXODI.COM
NETX.EXE

NETWARE USING VLM (3.12)
LSL.COM
XXXX.COM
IPXODI.COM
VLM.EXE

Using AppleShare and NetWare simultaneously

AppleShare and NetWare are both ODI stacks, and therefore install very similar files. The key to getting them to run simultaneously is to integrate these files into one set which can be used by both applications. If NetWare is already installed, a standard installation of AppleShare should automatically make the proper changes.

DOS-level Files installed by NetWare
C:\\NWCLIENT\\STARTNET.BAT-->batch file which loads the netware drivers listed above
C:\\NWCLIENT\\NET.CFG-->configuration file for LSL.COM
C:\\NWCLIENT\\LSL.COM
C:\\NWCLIENT\\XXXX.COM-->MLID
C:\\NWCLIENT\\IPXODI.COM-->ipx/spx protocol driver
C:\\NWCLIENT\\NETX.EXE or VLM.EXE

DOS-level Files installed by AppleShare
C:\\APPLE\\A_SHARE\\ATDRIVER.BAT

C:\\APPLE\\A_SHARE\\NET.CFG
C:\\APPLE\\A_SHARE\\LSL.COM
C:\\APPLE\\A_SHARE\\XXXX.COM-->MLID
C:\\APPLE\\A_SHARE\\ODI.EXE-->AppleTalk protocol driver

AUTOEXEC.BAT with NetWare+AppleShare
The AUTOEXEC.BAT should start with the following 2 lines:

call C:\\NWCLIENT\\STARTNET.BAT
call C:\\APPLE\\A_SHARE\\ATDRIVER.BAT

They need to be loaded in this order, or AShare will not be able to find the LSL.COM

ATDRIVER.BAT with NetWare installed

rem C:\\APPLE\\A_SHARE\\LSL.COM
rem C:\\APPLE\\A_SHARE\\XXXX.COM
C:\\APPLE\\A_SHARE\\ODI.EXE

The first 2 lines are remarked because these files are already being loaded by the STARTNET.BAT for NetWare. Thus, we end up with the combined drivers loading in the following order:
C:\\NWCLIENT\\STARTNET.BAT
C:\\NWCLIENT\\NET.CFG
C:\\NWCLIENT\\LSL.COM
C:\\NWCLIENT\\XXXX.COM-->MLID
C:\\NWCLIENT\\IPXODI.COM
C:\\NWCLIENT\\NETX.EXE or VLM.EXE
C:\\APPLE\\A_SHARE\\ODI.EXE

Another way to go about it is to completely remove the ATDRIVER.BAT and the corresponding call statement in the AUTOEXEC.BAT and add the C:\\APPLE\\A_SHARE\\ODI.EXE line to Novell's STARTNET.BAT

Sample NET.CFG with NetWare installed

Note: when NetWare is installed, AppleShare uses the LSL.COM and its configuration file (NET.CFG) from the C:\\NWCLIENT directory, not the C:\\APPLE\\A_SHARE\\ directory.

Sample:

```
#
# Configuration file for xxxx
# Unknown NIC
#
Link Support
  Buffers 10 628
   MemPool 16K
Protocol AppleTalk
   DEFAULT xxxx
  AARP xxxx H(0001) L(6) B(090007FFFFFF)
Link Driver xxxx
  FRAME ETHERNET_SNAP
   FRAME ETHERNET_802.3
   PROTOCOL IPX 0 ETHERNET_802.3
   PROTOCOL APPLETALK 80007809B ETHERNET_SNAP
  PROTOCOL AARP 80F3 ETHERNET_SNAP
   INT 10
   PORT 300
```

This sample is the same as the default NET.CFG that AShare uses when no other network software is involved. The NET.CFG for NetWare will contain additional sections which are only for use by NetWare. One of these sections is titled "NetWare DOS Requester". Installation of Ashare will not affect these sections, and thus they are not of concern when installing AppleShare. The important lines to look for in here are the Ethernet_SNAP frame statement and the Appletalk protocol statement.

Apple Share and NETX.EXE

There is an error in the PROBLEMS.WRI file for AppleShare client in regards to using Ashare with Novell 3.11 or earlier, which uses NETX.EXE.

It says: NETX.EXE, the NetWare connection utility, does not work with AppleShare Client for Windows. NETX, and similar network connection utilities, are written for other networks and are specific to their respective networks. These utilities cannot be used for connecting to a server of another type, such as an AppleShare server.

First of all, AShare does not even use NETX. It only uses the LSL and the MLID from the STARTNET.BAT file. Ashare uses its own ODI.EXE to connect to an AppleShare server.

In most cases, NetWare clients will have a line in the autoexec.bat which reads F:login. When NETX is loaded, it automatically connects to the first available server, unless otherwise specified. Then the login program on the server (F:) must be run in order to access files. NetWare mounts drives on drive letters which fall after the drive specified in the lastdrive statement. Therefore, lastdrive has to be set to E in order for the first NetWare server to mount on drive F:.

When AppleShare is installed it changes the lastdrive to z. This leaves no drives after the lastdrive to mount the netware server. Simply changing the lastdrive to E will not really work, because that only leaves drives D: and E: for use with ashare, and if they have a cd rom, only one of these will be available. What must be done is to change the lastdrive to something like m. This will cause the netware server to attach to drive N:. At this point, if they have F:login in the autoexec, it will give the message "bad command or file name." Simply change the F to whatever drive the server has used--in this case N:.

MemPool

This line (in net.cfg) specifies the amount of memory which is allocated to the network card driver (MLID). In some cases, increasing the amount of memory allocated can solve problems involving multiple protocol stacks. By default , the mempool line in the link support section reads," MemPool 16k". this value can be set as high as 64k. If it is set to a value higher than this, it will only allocate 64k.

Windows for Workgroups

NDIS

NDIS (Network Driver Interface Standard)

Microsoft networks (Windows for Workgroups and Windows NT) use NDIS-type drivers instead of ODI. All of the network drivers involved with Windows for Workgroups load when Windows starts. Windows for Workgroups can also be configured to use ODI drivers which load at the DOS level.

Aside from Microsoft products, many TCP/IP stacks use NDIS. AppleShare, however, can only be configured to work with Windows for Workgroups NDIS. It will not recognize any other NDIS- type drivers during installation. If AppleShare is to work with these TCP/IP stacks, the TCP/IP must be configured to work with ODI.

Installing AppleShare to work simultaneously with a Windows for Workgroups network

There are 2 ways to install AppleShare so that it will co-exist with Windows for Workgroups networking software.

1. Install AppleShare over an existing Windows network so that AShare uses NDIS.

2. Install AppleShare while no windows network is configured and then configure windows to use the ODI drivers which AShare installed. Installing AppleShare using NDIS is covered in the AppleShare manual.

Configuring Windows for Workgroups to use ODI

1. Install AppleShare using standard installation while no WFWG net is configured

2. Make sure that AppleShare is working properly

3. Go to the Network group from the program manager and choose Network Setup

4. In the window that follows, click on the "Networks" button.

5. Select "Install Microsoft Windows Network" and click "ok"

6. On the next screen, choose "drivers"

7. choose "add adapter"

8. Choose the approprate network card from the list and click OK NetBeui and IPX/SPX compatible transport protocols are installed. TCP/IP software can also be obtained from Microsoft and installed.

9. Highlight the adapter name shown in the window and click "setup"

10. Change the driver type to "ODI Driver" and click OK . When finished, click "close". Then click OK

11. Windows will prompt you to insert a username and password for the network and then ask for the necessary Windows disks.

12. When finished, Windows will prompt you to restart your computer.

13. While DOS is booting, you will receive a message which reads "ERROR: cannot find LSL". Press any key to continue.

14. Use the edit command to edit the autoexec.bat. The first three lines in the AUTOEXEC.BAT will read:
C:\\WINDOWS\\net start
C:\\WINDOWS\\odihlp.exe
call C:\\APPLE\\A_SHARE\\ATDRIVER.BAT
The order of these lines needs to be changed so that it reads:
C:\\WINDOWS\\net start
call C:\\APPLE\\A_SHARE\\ATDRIVER.BAT
C:\\WINDOWS\\odihlp.exe

15. Save this file and restart the computer.--installation is complete. If an error 58 occurs while starting windows, the incorrect adapter is chosen in windows.

MemPool

This line (in net.cfg) specifies the amount of memory which is allocated to the network card driver (MLID). In some cases, increasing the amount of memory allocated can solve problems involving multiple protocol stacks. By default , the mempool line in the link support section reads," MemPool 16k". this value can be set as high as 64k. If it is set to a value higher than this, it will only allocate 64k.

TCP/IP

TCP/IP packages come in 2 varieties--NDIS and ODI. AppleShare client for windows will only work with ODI-based TCP/IP. Normally, TCP/IP software which uses NDIS drivers can be configured to work with NetWare, or ODI drivers. This is the key to getting NDIS TCP/IP to work with Ashare.

Some examples of NDIS TCP/IP packages:

- Artisoft LANtastic
- Banyan Vines
- DEC Pathworks
- Microsoft TCP/IP for Windows for Workgroups

Some examples of ODI TCP/IP packages (these are configured for ODI by default and will easily work with AShare):

- Novell's LAN Workplace for DOS
- NetManage's Chameleon/NFS installation
- Trumpet Winsock
- TCP/connect II

Sample batch file (atdriver.bat) for loading AppleShare with an ODI-based TCP/IP stack:

C:\\apple\\a_share\\lsl.com
C:\\apple\\a_share\\XXXX.com (mlid driver)
C:\\odipkt.com (or whatever the TCP/IP driver name is)
C:\\apple\\a_share\\odi.exe

Typical LINK SUPPORT AND LINK DRIVER of NET.CFG for tcp/ip follows:

```
LINK SUPPORT
  MEMPOOL 64k
  BUFFERS 6 1600
  MAX STACKS 6
LINK DRIVER 3C5X9
  INT 10
  PORT 300
  FRAME ETHERNET_II
  FRAME ETHERNET_SNAP
  PROTOCOL IP 800 ETHERNET_II
  PROTOCOL ARP 806 ETHERNET_II
  PROTOCOL RARP 8035 ETHERNET_II
  PROTOCOL APPLETALK 80007809B ETHERNET_SNAP
```

PROTOCOL AARP 80F3 ETHERNET_SNAP

Binding TCP/IP protocols in the net.cfg

The following lines must be added to the link driver section of the net.cfg in order to use TCP/IP:

Link Driver XXXX
  Frame Ethernet_II
  Protocol IP 800 Ethernet_II
  Protocol ARP 806 Ethernet_II
  Protocol RARP 8035 Ethernet_II
Without these lines, the tcp/ip software will load, but will not be functional on the network.

Max Stacks

This line allows multiple protocol stacks to access the same ethernet card. Without fail, the Max Stacks line must be added to the Link Support section of the net.cfg in order to get appleshare and tcp/ip to work simultaneously. If the Max Stacks line is absent, the resulting error will read, "LSL out of resources" when either the ODI.EXE or the tcp/ip packet driver loads. The line should read: "Max Stacks 6" or "Max Stacks 8"

MemPool

This line (in net.cfg) specifies the amount of memory which is allocated to the network card driver (MLID). In some cases, increasing the amount of memory allocated can solve problems involving multiple protocol stacks. By default , the mempool line in the link support section reads," MemPool 16k". this value can be set as high as 64k. If it is set to a value higher than this, it will only allocate 64k.

Apple IIe: Printing to Networked Printers

I have an Apple IIe network problem. I have a printer network only with no file server. The school district wants to use the printer network with its 5.25-inch disk drives. There are about 50 labs with 20 to 25 Apple IIe systems in each lab.

I created a Chooser and Menu program "startup disk". I copied the necessary files and ATINIT to let the startup disk auto-select the networked printers. We found a public-domain menu program that requires only 1.5K. This lets the Chooser be part of the menu and lets teachers and students (especially K-3) select program without using pathnames.

I understand the AppleTalk network process and the need for the 3.5-inch drive. However, why can't we also provide support for the Apple IIe and the 5.25-inch drives?

This article has been archived and is no longer updated by Apple.
The only issue with using 5.25-inch drives for the described environment concerns disk space. After adding ProDOS 8, Chooser.II (with associated files), and ATINIT, the remaining space is all that is available for applications and data files on the startup disk. This means that there is approximately only 60K available for applications on a disk configured with the needed resources for network printing.

For a printer choice to be retained, you need run Chooser.II only once, as long as the selected printer maintains the same name and stays available on the network. The selected printer is stored in the ATINIT file of the disk that contains Chooser.II. On subsequent startups with that disk, the printer that was previously selected becomes the default printer. Thus, Chooser.II is not required to be run every session.

If only one 5.25-inch drive is available and if applications and/or data files larger than 60K are to be used, it is possible to start up with the disk described above, then switch (without restarting) to a second disk containing the larger application or data file. We do not know of any menu programs that can launch an application on a second disk, although such a program would not difficult for an Apple II programmer to write.

However, since Chooser.II needs to run only once (unless something about the printer changes), alternate methods of launching an application from the second disk can be considered. One example would be an Applesoft program that launched the menu program. By giving the Applesoft program a simple name (like MENU) and placing it in the main directory, the students would be able to switch disks, type RUN MENU, and then select the application desired.

iTunes 1.0: Sony PlayStation Discs May No Longer Appear After Installing iTunes

After installing iTunes 1.0, Sony PlayStation and other discs may no longer appear on the desktop due to the version of Foreign File Access included with Mac OS 9.0 or 9.0.4, and the Apple CD/DVD Driver installed by iTunes.
This article has been archived and is no longer updated by Apple.

Symptom

When you insert a Sony PlayStation disc a dialog box appears with a message that asks if you want to initialize the disc. After clicking Eject, the audio partition of the disc appears on the desktop.

Solution

Download and install Mac OS 9.1 to get the latest version of Foreign File Access.

LaserWriter IINTX: Setting Baud Rate to 19.2Kb

I have a LaserWriter IINTX on an Apollo workstation network. Initially, I direct-connected (9600 baud) the LaserWriter to a print server to download the PostScript file that sets the printer to 19.2K baud.

Is a hardware setting available for this 19.2K baud setting, perhaps a jumper inside the LaserWriter IINTX or switch settings? This would eliminate the need to download the file.

This article has been archived and is no longer updated by Apple.
The only way to set the baud rate of the LaserWriter IINTX to 19.2K baud is by sending a PostScript program to the LaserWriter. For reference, here is the PostScript program:

```
serverdict begin 0 exitserver
statusdict begin 25 19200 64 setsccbatch
```

For a more detailed description of this program and the options it can change, see page 122 of the "LaserWriter IINT/NTX Owner's Guide."

Macintosh: "Problem With Target Device. Error Code -7932" Alert

You should choose a slower burn speed if an alert box with a -7932 error message appears.
This article has been archived and is no longer updated by Apple.

Symptom

When you try to burn a CD an alert box with this error message appears:

> "There was a problem with the target device. Error code -7932."

Figure 1 Alert box with error message

Solution

This alert may appear if you are using media of marginal quality, or if you have a slower CD-R drive set to burn at maximum speed.

Try a different kind of disc, or a different brand or manufacturer of disc.

In iTunes, set the burn speed to something lower than the maximum setting, for example 4X or 6X.

If using CD-RW discs, only use CD-RW discs that are rated from 1x to 4x speed. The CD-RW drive in your computer cannot write to High Speed CD-RW discs (4x to 10x speed). Although the drive cannot write to High Speed CD-RW discs, it can read them.

iMac (Early 2001): What‘s New and Different

This article describes what is new and different with the iMac (Early 2001) computer.

This article has been archived and is no longer updated by Apple.

- CD-RW in 500 and 600 MHz models
- Two FireWire ports on all models
- Faster processors, up to 600 MHz
- Larger hard drives, up to 40 GB
- New styles including Blue Dalmatian and Flower Power, in addition to Indigo and Graphite.
- Theater mode now available in individual windows, as well as full screen

Macintosh SE: Models After July 1988 Can Take DIP SIMMs

Concerning the Macintosh SE, are we using (or have we ever used) DIP SIMMs? I was wondering ifthere might be a physical interference problem with some Ethernet cards if this were the case.

This article has been archived and is no longer updated by Apple.
Originally, Apple did not use DIP SIMMs in the Macintosh SE, because they did not fit. However, in July 1988, we revised our SIMM strategy for the Macintosh SE and began shipping the DIP SIMMs with the Macintosh SE. The Macintosh SE logic board was revised, and a jumper added that lets you put DIP SIMMs in banks 3 and 4 (the two frontmost banks), and still have room to install an option board.

This information is documented in the "Technical Procedures" manuals and in a service notice sent to Apple dealers in July 1988.

Macintosh: Front End for Telemail or MCI Mail

I am looking for a Macintosh software package, besides Desktop Express, that can act as a front end for either Telemail or MCI Mail.

This article has been archived and is no longer updated by Apple.
You might be interested in Software Ventures' MicroPhone II (which has an MCI Mail CCL). Prometheus offers Acknowledge (a toolkit for programming an interface for MCI Mail and Telemail) and Macknowledge, software for end users with scripting capabilities. Macknowledge comes with an MCI Mail button ready to use.

For more information, search on "Software Ventures" or "Prometheus Products".

Mac OS 9: How to Burn a CD and Choose a Format

This document explains how to burn a CD using a CD-R or CD-RW drive and explains which disc format may be most appropriate for your needs.
This article has been archived and is no longer updated by Apple.
Important: The information in this document assumes you have installed iTunes 2 or Authoring Support 1.1.3 or later and are using Mac OS 9. Both are available for download from Apple Software Downloads (http://www.apple.com/swupdates/). If you are using Mac OS X, see technical document 61339 "**Mac OS X: About Burning Data Onto CDs**"

Creating CDs

If your Mac has a recordable disc drive, you can create your own CDs in several different formats.

You use blank CD-R or CD-RW (read/write) discs to create your own CDs. Once a CD-R disc has been recorded, or "burned," you cannot modify the disc or any of the files on it. The discs you create are "single-session" CDs. You can burn CD-R discs only once; any extra space on the disc cannot be reused or recovered.

If you want to use a CD-RW disc that already has files on it, you must erase it first. Many CD drives in earlier computers cannot reliably read CD-RW discs. For better compatibility, use CD-R discs instead.

How to Burn a CD

1. Insert a blank disc into the CD recording drive. A dialog box appears.
2. Type a name for the disc in the Name field.
3. Choose a disc format from the Format pop-up menu. For information about the formats, see the "Choosing a Disc Format" section, below.
4. Click Prepare. A disc icon appears on the desktop.
5. Drag the files and folders you want to save on the disc to its icon. See Note 1.
6. When the files and folders are finished copying to the disc icon, arrange them exactly as you want to see them when the disc is burned**.** Once you burn a disc, you cannot change the placement of files or folders or their names. See Notes 2 and 3.
7. Click the disc icon, then choose Burn CD from the Special menu. See Note 4. A dialog box appears.
8. Click Burn. The disc is initialized and the files and folders are saved on the disc. This process takes several minutes. See Notes 5, and 6.

Choosing a Disc Format

You can choose from three disc formats when you create a CD. Each has a purpose, which is outlined here.

Standard (HFS+/ISO 9660)

Choose Standard format if you plan to use the disc with Macintosh computers or with both Macintosh and non-Macintosh computers. This format may also work with some later MP3-CD players.

Standard format is a hybrid of both Mac OS Extended (HFS Plus) and ISO 9660 formats. When read on most Macintosh and Windows-compatible computers, filenames appear as they do on any other disk. See Note 7. When read as an ISO 9660 disc on other computers, filenames appear in all uppercase characters, and they may also be shortened to fit the ISO 9660 level 1 standard (eight characters followed by a period followed by three characters, or 8.3).

CD-R or CD-RW media can be used with this format, though some earlier computers may not be able to read a CD-RW disc.

iTunes (Audio CD)

Choose iTunes format if you want to play the disc in a CD player. The CD should also work in any computer that can play audio CDs.

The iTunes application program opens when you choose this format so you can create your audio CD using music from your music library.

You should only use CD-R discs when creating audio CDs. Few CD players can read CD-RW discs.

MP3 CD (ISO 9660)

Choose MP3 CD format if you plan to use the disc only with non-Macintosh computers or if you have an MP3-CD player. See Note 8.

You generally only choose this format to save MP3 files on a disc, but you could use it to save any data file. Most computers and MP3-CD players can read discs that use the ISO 9660 format. If you plan to use the disc only with Mac OS or Windows-compatible computers, you

should use the Standard format instead.

On computers using Mac OS X, and on Windows-compatible computers, filenames on these discs appear as they do on any disk. On computers using Mac OS 9 or on earlier computers, filenames appear as all uppercase characters. They may also be shortened to fit the ISO 9660 level one standard (eight characters followed by a period followed by three characters, or 8.3).

CD-R or CD-RW media can be used with this format, though earlier computers and MP3-CD players may not be able to read CD-RW discs.

Notes

1. Files written to the CD are temporarily stored on your hard disk. Depending on the size of the blank CD, your files, and your hard disk, you may need as much as twice the capacity of the CD in free space on your startup disk. For example, if you are using a 650 MB CD-R disc you should make sure that your startup disk has at least 1.3 GB of available space.

2. When you create a Standard format CD, the size and location of the disc's window, whether or not the disc's window is open, and the position of all the icons are recorded on the disc. Make sure the disc is how you want it before recording it. If you choose to create an MP3 (ISO-9660) or iTunes audio disc, this extra information is not retained.

3. The names of files and folders on the burned disc may be different from what you see when you prepare the disc. Depending on the disc format you choose, files and folders may have truncated names, or be in all uppercase characters.

4. If you decide not to burn a CD that you have prepared in step 6, drag the disc icon to the Trash instead of choosing Burn CD from the Special menu.

5. If you cancel while the disc is being burned, the CD will be incomplete and unreliable. You should not use it.

6. The length of time it takes to create a disc depends on the blank media you use, and the size and number of files on the disc.

7. On earlier versions of the Mac OS or Windows a Standard format disc may appear only as an ISO 9660 disc.

8. The MP3 CD format may not work on some earlier MP3 players.

PrintMonitor: Setting PrintMonitor Window Preferences

This article explains how to make the PrintMonitor window appear when printing under Mac OS 9 and earlier.
This article has been archived and is no longer updated by Apple.
Some third-party printer drivers may not work with the Desktop Printers feature of the Mac OS, which can provide a listing of queued print jobs.

If you need to view queued print jobs, disable desktop printing and set the PrintMonitor window to appear automatically when printing, as outlined below:

1. Use the Extensions Manager control panel to disable the Desktop PrintMonitor and Desktop Printer Spooler system extensions.

Figure 1 Extensions Manager control panel

2. Open PrintMonitor, located in the Extensions folder.

3. Choose Preferences from the File Menu.

Figure 2 PrintMonitor preferences

4. Click Yes to enable the "Show the PrintMonitor window when printing" option, then click OK.

5. Restart the computer.

Macintosh: RGB-To-NTSC Video Conversion Options

I work at a TV station and am researching the best solution for recording 24-bit images from my Macintosh IIcx to videotape. I am interested in the Display Card 8/24 GC as a solution.

I have also considered the RasterOps 364 board that lets the Macintosh display real-time, 24-bit images on the Macintosh monitor from a video source. However, I do not know if this card offers the ability to record Macintosh video onto tape.

I am aware that the cards from Orange Micro, TrueVision, and Mass Micro may also be solutions. However I am not familiar with these cards and their features. If you can provide me with any info (or an opinion) I would appreciate it.

This article has been archived and is no longer updated by Apple.
There are three approaches to placing Macintosh images into the NTSC world:

- A video card with onboard NTSC output. RasterOps, SuperMac, Orange Micro, Computer Friends, Mass Micro, and others make Macintosh video cards that provide NTSC output directly from the cards.

- An RGB-to-NTSC converter box. RasterOps and ComputerVideo make RGB-to-NTSC converter boxes that work with Apple's color video cards, both the new ones and the original 8-bit video cards. RasterOps' converter also works with their 208, 264, 364, and 16PC cards. TrueVision also provides a RGB-to-NTSC converter box for their video cards. However, it does not work with the Apple video cards.

- A scan converter. RGB Spectrum builds a scan converter that works with most Macintosh 640x480 video cards.

The card providing onboard NTSC output must have all the necessary circuitry built on the NuBus video card. These are the simplest to install and use. There are connections on the cards for connecting the NTSC video signal coming from the card directly to the NTSC destination device. This usually uses an RCA-type phono-plug-to-phono-plug connection. The various cards provide a variety of features, from only video out to video overlay to frame grabbing to special video effects.

Note: In this article, the reference to frame grabbing indicates the ability to grab a frame of video in 1/30 of second. Scanning indicates the need for more time to acquire the image. This generally requires using a video camera for input, because most freeze-frame images are not usable for source material. The issue concerns the lack of video sync during freeze-frame mode.

There is currently one RGB to NTSC converter box available. Tech Comm has not been able to test this box, so we are unable to provide additional details. However, it appears that it should work correctly with the new video cards when the correct cable is used. It does work with the older 8-bit Macintosh color video cards when used with the interlace utility Apple has made available. The box is from ComputerVideo and is called Video NTSC Encoder.

RasterOps has announced The RasterOps Video Expander box, which is listed as compatible with the new Apple video cards. The RasterOps box provides both composite and S-Video (for S-VHS, HiBand 8mm and ED Beta) output signals. This converter also requires the correct cable to be used. Again, Tech Comm has not had the opportunity to test this card with the new video cards. Beyond the conversion to NTSC, these converter boxes do not provide any additional features to the video card that is used. These boxes require the signal coming from the cards to be in the NTSC interlaced mode.

For the finest conversion of RGB to NTSC, a scan converter is required. They are far more expensive than the converters mentioned above. Scan converters are used to create the highest-quality broadcast image. Scan converters not only convert the RGB signal to NTSC, they also eliminate the flicker associated with horizontal single-pixel lines and provide aspect-ratio conversion, color-bar generation, video transitions, freeze frame, and video mixing--all at the best available quality. The scan converters take the high scan rate RGB signal directly from the video cards, convert it to a digital frame buffer, do their functions digitally, and reconvert the image in an analog NTSC signal. This lets you do a function similar to Apple's 8-bit convolution on 24-bit images.

The RasterOps 364 does not provide NTSC video output without the use of the Video Expander box. In this respect, it is the same as the Display Card 8/24 GC. The frame grabbing ability and the live video on the Macintosh RGB display, however, do set it apart from the Display Card 8/24 GC. The 364 card does not provide the ability to overlay computer graphics on top of the live video. The live video window can be placed on top of a graphic background. None of the background will be seen through the live video image. The live video window is resizable.

The NuVista cards from TrueVision also provide frame grabbing from a video source. To lay the image back to videotape, the TrueVision VIDI/O converter box is required. The NuVista are not designed to provide live video images on the Macintosh RGB screen. Instead they provide the ability to overlay the Macintosh graphics on top of the video image. This composited image must be viewed on an NTSC screen.

Mass Micro provides a two-card set, the ColorSpace III and ColorSpace F/X cards. The ColorSpace III provides NTSC output of a Macintosh 8-bit image. It can also overlay the Macintosh graphics on top of video fed into the card. This composited image will appear on the NTSC device. Limited, non-real-time scanning can be accomplished. With the addition of the F/X card, a variety of video special effects can be achieved with the video signal being sent to the Macintosh.

The video image can be compressed, stretched, flipped, and so on in real time for use in the NTSC world. The F/X card can also frame grab from the incoming video in 24-bits. With the ColorSpace IIi and F/X cards the single-pixel line flicker problem is addressed. They do not use convolution as Apple does. Rather, they have devised their own method of addressing this NTSC issue.

The Orange Micro Personal Vision card offers frame grabbing and the ability to display incoming video on the Macintosh RGB screen. The Personal Vision card does not have an NTSC video output on the card. This cards relates most to the RasterOps 364 card. However, we don't know of any RGB-to-NTSC converter box for the Personal Vision card.

Some of the video cards that have onboard NTSC video output also offer the ability to overlay the Macintosh graphics on top of incoming video to provide a composite image at the NTSC output. This feature needs to be checked for any card being considered for combining video sources with Macintosh graphics.

Power Mac G4: iMovie and iDVD Restore or Reinstall

iMovie and iDVD are preinstalled on the computer's hard disk, and are included on the Apple Software Restore discs that come with the computer.
This article has been archived and is no longer updated by Apple.

Symptom

There are no installation discs for iMovie or iDVD.

Solution

For Power Mac G4 (QuickSilver) and (QuickSilver 2002) computers

iMovie and iDVD are preinstalled on the computer's hard disk. If you delete iMovie, iDVD, or parts of these applications, and then later decide you want to use either of them, you may restore the hard disk by using the Apple Software Restore discs that came with the computer.

Instructions for using this software are available in the "Restoring Your Computer's Software" section of the "Setting Up Your Power Mac G4" manual.

Reinstalling iMovie, iTunes, or iDVD Without Erasing

For more information on installing this software, refer to technical document 106451: "**Apple Software Restore: How to Install Reinstall Parts Without Erasing the Hard Disk**"

For Power Mac G4 (Mirrored Drive Doors)

iMovie, iTunes, and iPhoto are included as part of the Mac OS X 10.2 Installation disc. If you delete any part of these applications and then later decide you want to use them you can reinstall them by following these steps:

1. Insert the Mac OS X Installation disc 2.
2. Double-click "AdditionalApplications.pkg".
3. Type in your password, and click OK.
4. Click Continue at the Welcome to the Additional Applications Installer.
5. Select the destination disk, and click Continue.
6. Click Install.

Note: The additional applications cannot be selectively installed. This will reinstall iMovie 2.1.2, iPhoto 1.1.1, iTunes 3 and Acrobat Reader 5.0.5.

Modula 2: Available for the Macintosh (6/97)

Is there a Modula 2 vendor for the Macintosh?
This article has been archived and is no longer updated by Apple.
We found two sources of Modula-2 Power System-Modula 2 and MetCom Modula-2.

Pecan Software Systems's Power System-Modula 2 is a complete development environment with powerful programming tools along with a Modula-2 compiler. Power System-Modula 2 adheres to Wirth's Third Edition, separate compilation of modules, conditional compilation, nested include files, process synchronization, sets with up to 4080 elements, access to low-level system calls, extensive module library (source available) support packages available (including Pascal to Modula-2 translator, software tools), integratable with other languages (UCSD Pascal, Fortran-77, BASIC).

MetCom Modula-2 from Metropolis Computer Networks is an integrated Modula-2 development system comprised of a text editor, native code compiler, dynamic liner and source debugger.

A/UX: Porting C Code from SUN (9/94)

I have a question about Berkeley UNIX type compilers that run on a SUN/3 and similar machines. Would code compiled on a typical C compiler on a SUN run relatively unaltered (assuming recompilation) under A/UX?

Because we don't implement full Berkeley, would a program for a SUN system have to be radically re-written to run on a Macintosh running A/UX?

This article has been archived and is no longer updated by Apple.
A/UX is based on AT&T System 5.2.2. All C codes written on any System V.2.2 based system (use of standard System V.2 C compiler) should compile and run under A/UX without any change.

Since SUN/3 is based on BSD 4.[23] UNIX, there are differences between AT&T System V.2.2 and BSD UNIX 4.[23]. The area of difference includes ioctl() system call, signal handling, directory structure, and so on. Therefore, if the C code involves these differences, it needs to be modified to run on A/UX.

A/UX also supports UNIX 4.2BSD-style signals (software interrupts) and Berkeley UNIX 4.2-style network systems. For example, A/UX includes set42sig() so you can use the 4.2BSD signals. The Berkeley TCP/IP networking facilities like socket(), bind(), connect(), and so on are supported.

Now that the A/UX 2.0 and 3.0 kernel implements Berkeley file system (UFS), the system calls for UFS file system structure are available and supported.

Be aware that if the C code contains SUN specific (non-Berkeley or non-standard UNIX calls), it has to be re-written for A/UX. In short, porting C code to A/UX should not be a difficult task, although there are differences between System V.2.2 and BSD UNIX.

Business BASIC III: IF...THEN...ELSE

This article has been archived and is no longer updated by Apple.
The IF/THEN statement can give some unexpected results. The rules for IF/THEN are:

1. When the logical expression is true, the rest of the line is executed, except:

A. When there is an ELSE on the same program line, execution continues to the ELSE, then goes the next numbered program line.

B. If there is an implicit or implied GOTO, execution continues at the target line.

2. When the logical expression is false, execution continues on the next numbered program line, except:

A. When there is an ELSE on the line, execution continues after the ELSE.

The following examples might help explain some of these special cases:

Example 1:

```
10 if A = 0 then print "1" : print "2"
20 print "line 20"
```

Assuming A = 0 A <> 0

```
Results 1 line 20
2
```

If A equals 0, then the Print statements in line 10 are executed (rule 1). If A doesn't equal 0, then line 20 is executed (rule 2).

Example 2:

```
10 if A = 0 then 500 : print "1" : print "2"
20 print "line 20"
500 print "end"
```

Assuming A = 0 A <> 0

```
Results end line 20
end
```

If A equals 0, the Print statements in line 10 are never executed; then execution transfers to line 500 (rule 1B). If A doesn't equal 0, then line 20 is executed (rule 2).

Example 3:

```
10 if A = 0 then print "1" : goto 500 : print "2"
20 print "line 20"
500 print "end"
```

Assuming A = 0 A <> 0

```
Results 1 line 20
end end
```

If A equals 0, then the first Print is executed, then the execution is transfer to line 500 (rule 1A). If A doesn't equal 0, then line 20 is executed (rule 2). The last Print statement in line 10 is never executed.

Example 4:

```
10 if A = 0 then print "1" : print "2" : else print "3" : print "4"
20 print "line 20"
```

Assuming A = 0 A <> 0

```
Results 1 3
2 4
line 20 line 20
```

This is a classic example of how ELSE is used. Either execute Print 1 and 2 or execute Print 3 and 4 (rules 1A, 2A).

Example 5:

```
10 if A = 0 then 500 : print "1" : print "2" : else print "3"
20 print "line 20"
500 print "end"
```

Assuming A = 0 A <> 0

```
Results end 3
line 20
end
```

Print 1 and 2 in line 10 is never executed, because if A equals 0, then execution transfers to line 500 (rule 1B). If A doesn't equal 0, then the statements after the ELSE is executed (rule 2A).

Example 6:

```
10 if A = 0 then print "1" : goto 500 : print "2" : else print "3"
20 print "line 20"
500 print "end"
```

Assuming A = 0 A <> 0

```
Results 1 3
end line 20
end
```

If A equals 0, then Print 1 is executed, then execution is transfer to line 500 (rule 1B). If A doesn't equal 0, then the statements after the ELSE is executed (rule 2A). Print 2 statement is never executed.

A/UX: X Window System Symbolic Links

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I am installing X Windows. I have installed the software without problems, but when I run it, I get "X11BINDIR ENVIRONMENT ERROR". This is because I am using a second partition mounted under my own directory. I know that I need to do a symbolic link for some files, but I don't know to which ones and the manual has nothing about accessing X Windows under another directory.

When there is no room to install X in the root directory, why isn't this information included in the manual?

This article has been archived and is no longer updated by Apple.
If you installed X11 Window System (the Native X) on a separate partition, make sure the following files and directories are symbolically linked or copied to the right places:

```
ln -s /.../bin/X11 /usr/bin/X11
ln -s /.../lib/X11 /usr/lib/X11
ln -s /.../include/X11 /usr/include/X11
ln -s /.../lib/lib*X*.a /usr/lib
cp /usr/lib/X11/xterm* /usr/lib/terminfo/x
cp /usr/lib/X11/.x11start /
cp /usr/lib/X11/Sample.twmrc /.twmrc
```

Also, edit the .profile (for Bourne or Korn shell) or the .login file (for Csh shell) to include the /usr/bin/X11 directory in the search PATH.

The X Window System installation document does mention it requires 12MB of free disk space, and the Xinstall shell script also checks the available disk space before actually performing the installation.

For more information, refer to "Chapter 3 Install X11" in the "Getting Started With X Window System for A/UX" documentation.

Published Date: Feb 18, 2012

A/UX 2.0: Macintosh Applications Can Use 32-Bit Addressing

Does A/UX 2.0's 32-bit addressing extend to the "MultiFinder" process? That is, if I am running "normal" Macintosh applications under A/UX 2.0, do I have access to more than 8MB of memory space?

This article has been archived and is no longer updated by Apple.

Yes, A/UX 2.0's 32-bit addressing capability can be extended to the Macintosh applications which run under A/UX 2.0 MultiFinder Environment. However, the Macintosh application can access up to 16MB, because this is the maximum memory size allowed in Macintosh OS.

The size of the Macintosh application's memory address space can be changed via either ResEdit or Get Info. Note that there is a limitation on using the "Get Info" method; it lets you key no more than four digits. Therefore, use ResEdit if you require a change of more than 9999K.

To have your Macintosh applications run in the A/UX 2.0 32-bit environment, make sure you have sufficient virtual memory allocated before the session is started. There are two ways of controlling the size of the virtual memory allocation:

1) By assigning a value to an environment variable TBMEMORY. For example, "TBMEMORY=16m; export TBMEMORY" (or put them in the .profile file or .login file), logout then login again. This will create a 16MB virtual memory for MultiFinder.

2) By passing a flag when starting the "startmac" process. For example, edit the /mac/bin/mac32 file to have the "startmac" command line to read "/mac/bin/startmac -m16m &". This will create a 16MB virtual memory for MultiFinder.

The maximum feasible size for virtual memory is dependent on the environment (24-bit or 32-bit), and of course the size of the Swap space on the disk. For the 24-bit environment, the maximum virtual memory is 8MB; for the 32-bit environment the maximum virtual memory is 256MB.

System performance, however, will degrade if the virtual memory is much larger than the physical memory present in the system because a lot of paging and swapping activities will take place. A good rule of thumb is to keep virtual memory no larger than twice the size of physical memory present in the system.

A/UX 2.0: How to Escape from a Hung Login Under X Windows

I created an interesting problem for myself. I was preparing a Macintosh IIfx with X Window and mistyped a line into the PATH variable. When I tried to log in, I hung. I was finally able to break out of the login process, but it was time-consuming and not very intuitive. The typo was /usr/lib/X11, instead of /usr/bin/X11. Obviously, this didn't let the process look in the right place for the software, so it wouldn't boot properly.

Do you have any suggestions?

This article has been archived and is no longer updated by Apple.

As we have tested the above X11 session scenario (login as "Guest" without the /usr/bin/X11 in the search PATH) we won't get into the "hung" situation. It is true that the screen displays, "Starting session for Guest...", if no one presses the Return key.

At that "hung" point, however, if you only press Return, the default X11 session will come up. The default X11 session includes a "Console" window, two "xterm" windows, and three X client applications (xlogo, xload, and xclock). If you have pressed any printable key then Return, it will bring you back to the Login dialog box.

As we examine the /usr/bin/X11/X11 script, the above behavior becomes clear, because the X11 script does check if /usr/bin/X11 is in your search path, then asks you if it should be appended to your search path. This is why the "Starting session for Guest..." message was waiting for your reply.

Note that the "x11debug.log" file will be created under the user's home directory, if any error is encountered. Check with that file for an explanation.

TA44054_AUX_Supported_Printing_from_UNIX__(TIL05896).pdf

A/UX: Supported Printing from UNIX (12/95)

This article describes printing features available to UNIX users.

This article has been archived and is no longer updated by Apple.
A/UX 3.0 supports both AT&T System V and Berkeley BSD printer spoolers. The default printer spooler now is the Berkeley printer spooler that supports printcap (/etc/printcap) and remote printing capability.

You can configure printcap to print to locally connected devices like a serially connected ImageWriter or LaserWriter, or remote printers like other UNIX systems with lpd or TCP/IP capable Laser printers.

For more detailed information on Berkeley printer spooler system, refer to the printcap(4), lpr(1), lpc(1M), lpd(1M), lpq(1), & lprm(1) manual pages, and the "Setting Up Accounts and Peripherals for A/UX" documentation.

Additionally, printcap can be configured to make connections to AppleTalk printers, by have lpd use the AppleTalk protocol stack that is part of A/UX.

The input/output filters for AppleTalk LaserWriter Printer are provided in the /usr/spool/lpd/AppleTalk directory. For those who need to create multiple AppleTalk LaserWriters access, be sure to follow the instructions included in the input filter file (ifiler).

NOTE: The "pipe" file and filter files under each individual printer directory must be owned by "daemon" and grouped by "daemon".

As an example, to print a file "test", to a LaserWriter named "Metro" on an AppleTalk network (assuming the LaserWriter has a printcap entry "metro|mt") the user may give the command:

lpr -Pmetro test
or lpr -Pmt test

If the "-P" option is omitted, A/UX will print to either the default printer chosen from CHOOSER, from "at_cho_prn", or from the value of environment variable PRINTER.

For information on AppleTalk printing, refer to the atprint(1), atstatus(1), at_cho_prn(1), & atlookup(1) manual pages. Also look at "A/UX Networking Essentials" and "A/UX Local System Administration" manuals.

Applesoft: Syntax error when the program is run

Applesoft requires the first byte in the program storage area be zero.
This article has been archived and is no longer updated by Apple.
Some machine language programs don't leave a zero, causing Applesoft to react strangely.

Initialize that byte, even if the program memory pointer has been changed by:

POKE PEEK (103) + PEEK (104) * 256,0

Business BASIC III: Errata for Reference Manual

This article has been archived and is no longer updated by Apple.
The following are errata for Business BASIC III manual # A3L0002/030-0122-00

Page iv...The correct page number for Chapter 6 is 159.

Page iv...The entries for appendices C and D are reversed. They should read:

C Alphabetic list of reserved word 236
D Variable maps 238

Page 27...The section on CTRL-5, -6, -7, -8, -9 should refer to page 139 of the Standard Device Drivers Manual.

Page 128...The information at the top of the page is missing periods. It should read:

)print using "+###.###"; 3.14159
+ 3.142

This spec, +###.##,

Page 151...The line at the top of the page should read:

DEF FN MODB(A)=int ((A - int (A / B) * B +.5)

Page 240...The information for Long integers is reversed. It should read:

Long integer 0 high byte
7 low byte

Page 329...The example that starts "print1;Apple" should read:

print #1;"Apple"

Prints text characters on the graphics display, starting at the cursor position.

If you used:

open #1,".Graphix"

to open the graphics driver. Cursor marks upper left corner of character's rectangular cell.

To send direct screen-control characters to the .Graphix driver:

print #1; chr$(19);chr$(13)

Page 322...KBD is described on page 121 instead of page 43.

Mac OS X Server 1.x: Downloading Updates

This article contains general instructions for downloading and installing updates for Mac OS X Server versions 1.x.

Note: This article does not pertain to Mac OS X Server versions 10.x, which were released in or after May 2001.

This article has been archived and is no longer updated by Apple.
If your Mac OS X Server computer does not have a connection to the Internet you must perform the following file transfers on another computer that does have a connection, and then copy them to your server computer.

If your Mac OS X Server computer does have an Internet connection follow these steps:

Using OmniWeb

1. Log in to the server as Administrator (or root).

2. Open the OmniWeb browser (/Local/Applications/Internet/OmniWeb.app).

3. Select the folder from the following directory; it contains the update you need:

http://download.info.apple.com/Apple_Support_Area/Apple_Software_Updates/English-North_American/Mac_OS_X_Server/

4. Command-click the appropriate.tar file and click OK in the dialog box that appears. This saves the file into your download directory (~/Library/OmniWeb/Downloads/)

5. In a Viewer Window go to the ~/Library/OmniWeb/Downloads/ directory. The easiest way to navigate to this directory is to type a ~ and press the Return key, then follow the directory structure down.

6. Single click the .tar and press Command+2. This opens the Contents Inspector. Click the Unarchive button and the tar file will be expanded in the current directory.

7. Using the Viewer in WorkSpaceManager, select the .pkg file. Then under the Tools menu choose Inspector/Tools. Make sure that "Installer" is the application selected to open this package.

(**Note**: The file name is the name of the component you have downloaded with the extension.pkg such as MacOSXServer.1.0.2.pkg . For the remainder of this article it will be referred to as .pkg).

8. Close the Inspector and double click the package to start the installer. This opens Installer.app. Click on the "Install" button to perform the installation. You are asked if you want to replace existing files; answer "Continue" to this question.

9. Shut down the computer by choosing Log Out from the File Menu and clicking Shutdown in the dialog box that appears.

10. Start the computer normally and the updated components are ready for use.

Using the command line

1. Log in as Administrator (or root)

2. Open Terminal.app

3. Download the updates for Mac_OS_X_Serer_OS from Apple's ftp server using the following commands:

```
ftp ftp.info.apple.com (Log in as "anonymous" and give your email address as password)
bin
cd Apple_Support_Area/Apple_Software_Updates/English-North_American/Mac_OS_X_Server/Mac_OS_X_Server_OS
get <insert name here>.pkg.tar
quit
```

Replace the string <insert name here> with the actual file name.

Note: To download files for other components of Mac OS X Server change Mac_OS_X_Server_OS to the appropriate folder such as QuickTime_Streaming_Server/ for QTSS

4. At this point the update will be in the home directory of the Administrator user. Keep a copy of this file in case you need it in the future. Type the following command to make a temporary copy of the update to work with: cp <insert name here>.pkg.tar /tmp

5. In the Viewer, go to the /tmp directory and single click the .pkg.tar and press Command+2. This will open the Contents Inspector. Click the Unarchive button and the tar file will be expanded in the current directory.

6. Using the Viewer in WorkSpaceManager, select the .pkg and then under the Tools menu, choose Inspector/Tools. Make certain that "Installer" is the application selected to open this package. Then install the software update by opening the package by double clicking it. This will open Installer.app. Click on the Install button to perform the installation. You will be asked if you want to replace existing files, answer "Continue" to this question.

7. Shutdown the computer by choosing Log Out from the File Menu and clicking the Shutdown button in the dialog box that appears.

8. Start the computer normally and the updated components will be ready for use.

A/UX 2.0: Virus Protection

What do you recommend for virus protection in the mixed A/UX-and-Macintosh OS environment?

This article has been archived and is no longer updated by Apple.

We haven't heard of any virus reports on A/UX machines. Most anti-virus programs like "Disinfectant" or "SAM" should run under A/UX. Just check with the vendor of the product you plan to buy to make sure it works in the A/UX environment.

QuickTime: Installer Download Requires Cookies

When I try to download either the Web or the stand-alone installer for QuickTme, my browser presents a dialog box asking me for a name and a password. Why can't I download QuickTime?
This article has been archived and is no longer updated by Apple.
In order to download QuickTime (both the Web installer and the stand-alone installer), your browser (and firewall or proxy server) must allow cookies. If you disallow cookies, you will not be able to download the software.

If your browser is configured to allow cookies and you are presented with a dialog box asking for a name and a password, contact your network administrator or service provider.

The cookie that is set in your browser is only in RAM, does not track any personal information, and is purged as soon as you quit your browser.

LaserWriter: All Printers on Network Need Same Driver

I have Version 6.0.1 of the LaserWriter driver and Laser Prep. After installing it on one of our machines, I get a message that the LaserWriter contains an incompatible version of Laser Prep that cannot be removed and that I should restart the printer.

Restarting the printer doesn't help. The LaserWriter in question is spooled using the AppleShare Print Spooler on an AppleShare server. When the spooler "picks up" the LaserWriter, it must be downloading the Laser Prep to the LaserWriter. The problem is that I am spooling LaserWriters for two departments on this spooler and don't want to update both departments to the new drivers.

Will I have to update everyone to System 6.0.5 and the 6.0.1 LaserWriter driver?

This article has been archived and is no longer updated by Apple.
The LaserWriter driver on the spooler determines the version needed by each workstation. Therefore, all printers captured by the spooler must use the same drivers. However, you need only update the users' drivers, not the system software. The 6.0.1 driver is compatible with Macintosh System Software 6.0.x.

In other words, if there are different versions of the LaserWriter Driver in your network on various Macintoshes, including System 7 versions, the printer will have to go through a lengthy process of reinitializing itself to a new version of the LaserWriter driver every time a different version is used in the printing process. In general, the best and most consistent approach is to update every Macintosh on the network with the highest version of the LaserWriter driver being used on the network.

AppleShare: Folder "View" Is Set by Owner

Is there any way to "set" an AppleShare file server, so that the folders and files are viewed by date instead of by folder as default?

This article has been archived and is no longer updated by Apple.
The "View" choice for a folder is set by the owner of the folder. Once the owner has made the change (view by date, for instance), users of the folder won't see a difference until the folder has been closed by the owner.

IBM 3476, 3477 Terminals: Emulation Alternatives

I have an IBM AS/ENTRY model A20 with 3476 B20 and 3477 D20 terminals. I would like to replace the terminals with Macintoshes.

Do you have technical information on those terminals, and are you aware of any products for the Macintosh to emulate those terminals?

This article has been archived and is no longer updated by Apple.
We are not sure about models B30 and D20. Here is what we got from IBM brochures:

IBM InfoWindow 3476 Monochrome Models EA and EG:

14-inch, low-glare etched flat screen
Choice of amber (EA) or green (EG) characters on a black background
Enhanced ergonomics
Low-cost, entry-level 5250 compatibility
Choice of three low-profile keyboards

IBM InfoWindow 3477 Monochrome Models FA and FG:

14-inch, low-glare etched flat screen
Choice of amber (FA) or green (FG) characters on a black background
Enhanced ergonomics
Full-function 5250 compatibility
Choice of two low-profile keyboards
Printer port for host or screen print

We don't know of any Macintosh programs that emulate the two terminals you mentioned, but because they are 5250-compatible, you can use one of the following alternatives:

Andrew Corp. provides a system of hardware and software for connecting to both the AS/400 and System 3x computers. Their product line includes MacTwin, NetAxcess, TokenAxcess, Boxer (protocol converter), and TCPAxcess.

IDEAssociates has a Macintosh product for connecting to AS/400 computers and to System 3x computers. IDEAcomm Mac version 1.0+ is the product's name.

Wall Data has a Macintosh product line for connecting to an AS/400. Their product line includes SNA*ps 5250 stand alone product, SNA*ps 5250 client, and SNA*ps Gateway.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Note: This article provides information about a non-Apple product. Apple Computer, Inc. is not responsible for its content. Please contact the vendor for additional information.

LaserWriter 2.0 ROM: Performance Enhancements

This article has been archived and is no longer updated by Apple.

The performance of the LaserWriter for many applications has been significantly improved in the new implementation of the LaserWriter software. The main areas of improvement are as follows:

-- PostScript interpreter

The PostScript interpreter is substantially (30 to 40 percent) faster than before. This improvement applies primarily to programs that are being interpreted from procedures already stored in VM; programs being interpreted from a file or string receive little benefit.

-- AppleTalk

Efficiency of AppleTalk communication has been improved by a buffer strategy that permits greater overlap between the work being performed on the LaserWriter and on the host. This is especially noticed when using Apple's Print Manager on the Macintosh, which sends relatively short (512 byte) blocks.

-- Throughput

Page throughput for many applications is significantly increased by a new printing strategy that permits imaging of a page to be overlapped with execution of the PostScript description for the next page. Formerly, page imaging and PostScript execution were performed serially; the imaging time (up to 6 seconds per page) was entirely wasted.

-- Compressed character mechanism

Page descriptions that print large characters may benefit from the compressed character mechanism. Large characters now are often obtained from the font cache, whereas formerly they were always produced by re-executing the character descriptions.

-- Font cashe

Characters may be retained in the font cache even after removal of the font definition from which they were generated. If the same font is later defined again, the cached characters will be found and used if they still exist. This depends on correct use of the UniqueID entry in the font definitions; see the discussion under 'Modifying and creating fonts' in the PostScript Language Tutorial and Cookbook.

-- Virtual memory

The total amount of virtual memory available is not exactly the same as in the original LaserWriter, although it is close to being the same. This may affect the maximum number of down-loaded and user defined fonts that can be present simultaneously. Note that PostScript page descriptions with large preambles can obtain significant VM space savings by making use of the packed array facility.

Macintosh: Support for External Floppy Drives

I want to use two Apple 90 mm (3.5-inch) external floppy drives with my Macintosh. I have tried to chain them together, but the system recognizes only the first drive in the chain. Can I use more than one external floppy drive?

This article has been archived and is no longer updated by Apple.

No Macintosh computer can work with more than one external floppy drive. Only the Macintosh SE and later computers can work with the Apple SuperDrive (Apple FDHD).

Computer	Floppy Disk Drive Configuration
Macintosh Plus	1 Internal (800K) and 1 External (400K or 800K)
Macintosh SE	1 or 2 Internal (800K or SuperDrive if upgraded) and 1 External (400K, 800K, or SuperDrive if upgraded)
Macintosh SE with SuperDrive	1 or 2 Internal (SuperDrive) and 1 External (800K or SuperDrive)
Macintosh SE/30, Classic, Classic II	1 Internal (SuperDrive) and 1 External (800K or SuperDrive)
Macintosh Color Classic	1 Internal (SuperDrive) and no External
Macintosh II, IIx	1 or 2 Internal (800K or SuperDrive) and no External NOTE: The Macintosh II must be upgraded to a IIx, or must use a PMMU, to support a SuperDrive.
Macintosh IIcx, IIci	1 Internal (SuperDrive) and 1 External (800K or SuperDrive)
Macintosh IIfx	1 or 2 Internal (800K or SuperDrive) and no External
Macintosh LC	1 or 2 Internal (SuperDrive) and no External
Macintosh LC II, LC III	1 Internal (SuperDrive) and no External
Macintosh IIsi	1 Internal (SuperDrive) and 1 External (800K or SuperDrive)
Macintosh IIvx	1 Internal and no External
Macintosh Quadra 610, 630, 650, 700, 800, 900, 950, Power Macintosh 4400, 5200, 5300, 5400, 5500, 6100, 6200, 6300, 6400, 6500, 7100, 7200, 7300, 7500, 7600, 8100, 8115, 8200, 8500, 8600, 9500, 9600, G3, G3 All-in-one, Twentieth Anniversary,	1 Internal (SuperDrive) and no External
Macintosh Portable	1 or 2 Internal (SuperDrive) and 1 External (800K or SuperDrive)
Macintosh PowerBook 100	No Internal and 1 External HDI-20 1.4MB floppy drive
Macintosh PowerBook 140, 145, 160, 165c, 170 180, 180c, 190, 190cs	1 Internal (SuperDrive) and no External
PowerBook Duo 210, 230, 250, 270c, 280c, 2300	No Internal and 1 External (with MiniDock)
Macintosh PowerBook 520, 520c, 540, 540c, 550, 1400, 3400, 5300, G3, G3 Series	1 Internal (SuperDrive) and no External
Macintosh PowerBook 2400	No Internal and no External
Macintosh Performa 200	1 Internal (SuperDrive) and 1 External (800K or SuperDrive)
Macintosh Performa 400, 405, 410, 430, 450, 460, 466, 467, 475, 476, 550, 600, 630	1 Internal and no External

Notes:

1. Floppy disk drives on some PowerBook computers are optional.
2. Some Apple computers that do not have a floppy disk drive, like an iMac computer, work with optional external floppy disk drives connected to the Universal Serial Bus (USB) port.

Ethernet: Preventing Macintosh IIci Performance Degradation

Apple engineering has discovered performance degradation under the following configuration:

- EtherTalk NB Revison K card

- EtherTalk 2.0.1 or 2.0.2 software

- Macintosh IIci

- On-board video and four or more colors (In 2-bit or greater mode).

This article has been archived and is no longer updated by Apple.
To avoid Ethernet performance degradation on a Macintosh IIci, choose from among these three options:

- Use an EtherTalk NB Revision L card (shipping since December of 1989).

- Do not use on-board video (i.e. use a video card)

- Use only black and white video (1-bit video)

If you're using EtherTalk software, the Ethernet performance can be improved somewhat by starting the Macintosh IIci in 1-bit video and later switching to 2-bit or more video. This workaround is effective when using EtherTalk software (AppleTalk), but not MacTCP software (like MacX.)

The Ethernet performance can also be improved somewhat if you start the Macintosh IIci in LocalTalk and then switch to EtherTalk. This doesn't help in the MacTCP case, unless you are running MacTCP over EtherTalk, rather than standard Ethernet.

Macintosh Finder: Print Directory Workaround

I have a problem printing a disk directory from the Finder while in "View by Name" mode (running System Software 6.0.5 with the LaserWriter 6.0.1 and 5.2 drivers).

Black areas are printed on the pages along with the correct information. Sometimes, the areas are narrow, running along the right side of the page. Other times, the areas are broad, running right through the middle of the page. It is NOT a problem with the toner cartridge, as the black areas have a definite pattern like a scaled graphic character.

This article has been archived and is no longer updated by Apple.
When you choose Print Directory for the directory of a folder or disk that has one or more locked files, and with the view set to something other than Icon or Small Icon, the pixels for the padlock are printed like fat bits on top of (or next to) the text. The size of the padlock (usually very distorted) varies.

You can work around the problem under MultiFinder by turning on background printing.

This has been fixed in System 7.

MacX: Key-Mapping Problem When Oracle Changes sysenvir to tty

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

I'm having a problem with the new MacX.

I was using a Macintosh SE with Extended Keyboard on LocalTalk going through a GatorBox Box. The host was a SUN workstation; OS was 4.0

When doing Xterm or accessing an Xwindow based Oracle database, certain keys didn't seem to be mapping -- A, D, M, and N. Also, numbers on the top of the keyboard weren't being mapped, but the numbers on the side key pad worked fine.

What's the scoop?

This article has been archived and is no longer updated by Apple.
If you logged on to the X Window-based Oracle database, it was changing the sysenvir to tty mode. In our own test, we changed the Oracle profile so the userid was TERM=PC. This solved the problem.

Published Date: Feb 18, 2012

AppleShare PC: Switching From PostScript to Epson

Are there any DOS batch files that will switch AppleShare PC print services from PostScript to Epson mode transparently as a pre-defined application is loaded, and then back again when the application is quit?

(The two applications in question are Smartterm and CrossTalk. Both are being used for All-in-1 emulation.)

Barring the batch files, do you have any other suggestions. It's unacceptable to me to have to access the ASPC chooser every time I want to use All-in-1?

This article has been archived and is no longer updated by Apple.
The easiest solution would be to establish two connections to the same LaserWriter. One connection can be set up to use PostScript, and print to LPT2 (or the first available). The second can then be set up to use Epson emulation and print to LPT3 (or the next available). You would then configure one application to print to LPT2 and the other to LPT3. (We have done this with AppleShare PC 2.0 and 2.0.1 and it works fine.)

The connections can be configured from DA to be established automatically on startup, so that you need only remember that printing to LPT2 uses PostScript and printing to LPT3 uses Epson emulation.

Macintosh-to-CA-Datacom/DB Access

I need to access a database on an IBM 3090. It's called DATACOM, by Computer Associates International. Can you help?
This article has been archived and is no longer updated by Apple.
CA-Datacom/DB is a database management system from Applied Data Research (ADR) which was acquired by Computer Associates International in 1988. Since then, CA has tried to merge Datacom/DB with its other DBMS product: CA-Universe. Prior to release 8.0, Datacom/DB did not provide SQL capability.

A terminal emulation program such as MacDFT would allow access to IBM hosts and databases. However, we assume you would like to access the database in the client/server fashion, such as what is offered by Data Access Language (formerly CL/1). We provide DAL servers for both VM/CMS and MVS/TSO. However, on VM/CMS, DAL servers only allow access to IBM's Structured Query Language/Data System (SQL/DS) and on MVS/TSO, only Database 2 (DB2). There is no adapter currently for CA-Datacom/DB.

For more information, search under "Computer Associates".

Macintosh IIfx: CDC Wren Hard Drive Compatibility (11/94)

Is there a way to connect a CDC Wren Series 7 94601 or CDC Wren Series 6 602 to the SCSI port of the Macintosh IIfx? Both hard disks need to be connected synchronously.

This article has been archived and is no longer updated by Apple.
We called Seagate Technical Support and asked them about the two drives mentioned above. They were aware of the CDC Wren 94601 but not the CDC Wren 602. There is a CDC Wren 94602 but it is not compatible with the Macintosh. Note: CDC is a division of Seagate.

There is a specific model of the CDC Wren 94601, the CDC MacWren 94601-1.2GM, that is, according to Seagate, compatible with the Macintosh IIfx; other models of the CDC Wren 94601 are not compatible with the Macintosh IIfx. Driver software and cables are available from a company called Ontrack (Technical Support: 612-937-2121; Sales: 800-752-1333).

Business Graphics III: HP Plotters

This article has been archived and is no longer updated by Apple.
Business Graphics III includes a set of drivers for different graphic plotters, one of which is the HP 7225A plotter. HP has since changed their product; the 7225A Plotter has been replaced by the HP 7470A plotter. To connect this new plotter to the Business Graphics III:

a. Use the Apple Modem Eliminator Cable (A3M0019) along with the cable supplied with the plotter (AMP 07470-60090).

b. Set the .printer driver to 1200 baud and one (1) stop-bit.

c. Set the plotter's switches as follows:

S2 S1 Y US B4 B3 B2 B1
0 1 0 0 0 1 1 1

d. Enter the command SET DEVICE HP 7225A to initialize the plotter from Business Graphics.

Macintosh IIfx: SCSI Port and Hard Drive Performance

How fast must a hard disk be to take full advantage of the speed (3 megabytes per second) of the Macintosh IIfx SCSI port?

This article has been archived and is no longer updated by Apple.
A hard disk drive with a sustained data transfer rate (not to be confused with "throughput") of 3 megabytes per second or faster will take full advantage of the improved performance of the Macintosh IIfx SCSI port.

This transfer rate is independent of the operating system. For example, there is no difference in the transfer rate when using A/UX.

Published Date: Feb 18, 2012

A/UX 3.0 Workstation Information (9/94)

This article contains a series of questions about using Macintosh IIci systems as A/UX workstations.

1) How many NuBus slots can be connected as 802.3 Ethernet ports?

2) What UNIX is A/UX based on?

3) What about the A/UX C compiler?

4) Does the current version of A/UX support menu-driven System Administration type of function?

5) Are the remote system administration utilities like "rdump" and "rrestore" supported in A/UX?

6) Does A/UX support Xerox's Ethernet (XNS)?

7) Does A/UX support RFC 943?

8) Does A/UX support RFC 951 (Bootstrap Protocol)?

9) How many physical layer supported connections can you have?

10) How many sockets per session can you have?

This article has been archived and is no longer updated by Apple.
Here are the answers:

1) In theory, up to 6 NuBus slots can be connected as 802.3 Ethernet ports.

2) The current version of A/UX 3.0 is based on AT&T System V2.2 UNIX with BSD 4.[23] extensions which include software signals and Internetwork facilities. It conforms to SVID (System V Interface Definition) and SVVS (System V Verification Suite). Also the System V3 Streams is supported in A/UX.

3) The A/UX C compiler is driven from the standard AT&T System V.2 C compiler. However, it is not ANSI C compatible.

4) The current version of A/UX does not support menu driven System Administration type of function.

5) The remote system administration utilities like "rdump" and "rrestore" are supported in A/UX.

6) Currently, A/UX 3.0 does not support Xerox's Ethernet (XNS), but a third-party might have solution on it, for instance the BSD 4.3 UNIX supports XNS protocol. Porting to any UNIX box should be easy.

7) RFC 1117 is pretty standard in Internet. It replaced the obsolete RFC 943. Basically, DDN Network Information Center (NIC) maintains the assigned network number for the Internet community, Class A network is assigned with numbers between 1 and 127, Class B network is assigned with numbers between 128 and 191, and Class C is assigned with numbers between 192 and 255. This is supported by A/UX.

8) RFC 951 (Bootstrap Protocol) describes an IP/UDP bootstrap protocol (BOOTP) that lets a diskless client machine discover its own IP address, the address of a server host, and the name of a file to be loaded into

memory and executed. The current version of A/UX 3.0 does not support bootp.

9) The number of physical layer supported connections can be up to the number of available NuBus slots. (That's 6 in Macintosh IIx.)

10) The number of sockets per session can be configured via "kconfig" to as many as the user wishes. However, for the sake of performance, more physical memory is needed if the number of sessions is increased. The default is 16.

Floppy Drive Port: Maximum Power Load (11/94)

I am interested in the Integrated Data Systems IDS-WIP series drive. It is a low-power, compact SCSI drive that gets its power from the external, floppy port.

Are there any possible problems with this drive? Would it invalidate Apple's warranty? They mentioned in its specifications that it uses from .25 to 1.5 watts maximum draw, depending on the size of the hard disk.

This article has been archived and is no longer updated by Apple.
The power budget of this port varies slightly with each of the Macintosh models, but the worst-case scenario follows. The combined load of all devices connected to the floppy drive ports shouldn't exceed the following:

+5 700 milliamps
+12 600 milliamps
-5 10 milliamps

Apple typically discourages using the floppy port in the way you describe. These ports were designed to support the 400K, 800K, and the 1.44MB Apple disk drives. The older Macintosh computers also had ROM support for the Apple HD20-- which provided its own power.

Because the drive you describe requires no physical modification to the Macintosh, powering a SCSI drive in this fashion would not void the warranty--unless the damage caused to the Macintosh is traced back to the drive.

A/UX: Quantum Pro-80 Requires Different Formatting (9/94)

I have been unsuccessful in installing A/UX 1.1.1 onto Quantum Pro-80 drives using the Apple HD Setup utility. I heard that there is a ROM difference between the Quantum drives I have and the ones Apple uses. My drives have Quantum ROMs, while Apple's have an Apple ROM. Have you heard of problems with Quantum drives?

This article has been archived and is no longer updated by Apple.
According to Quantum technical support, the Pro-80 drive is not compatible with the Quantum Q280 drive which is used in the Apple HD 80SC. They use their own ROM. The Apple HD Setup software cannot be used to initialize the Quantum Pro-80 drive.

To install A/UX onto a Quantum Pro-80 drive, find a third-party disk formatter to format and partition it for A/UX. A good example is SilverLining from La Cie Ltd.

A/UX: Change Process Priority with nice (1) and (2)

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

Apple gives a high priority or time slice to the mac32 process. I'm developing a product that needs to throw up a dialog saying that it's going to process data and then take over as much of the CPU's time as possible.

Do you have any tools and/or facilities to give priorities to specific tasks? Ultimately, I would like to shut off tasks like network deamons, cron deamons, and so on.

This article has been archived and is no longer updated by Apple.
A/UX supports both nice (1) and nice (2). These let you run or change the priority of a process.

nice (1), which is available from the command level, executes the specified command with a lower or higher CPU scheduling priority. Note that the nice built-in function in the C shell is different from /bin/nice, so be careful using nice. The superuser may run commands with priority higher than normal by using a negative increment. For example:

/bin/nice --15 wc /usr/dict/words

causes the program "wc" to be run with higher priority than a normal process. See nice (1) manual page for more details.

nice (2) is a system call to change the priority of a process. It adds the increment value (specified in the argument) to the value of the calling process. See nice (2) manual page for more details.

Farallon StarController: IIGS and IIfx Upgrade Information

Is there a known problem using Macintosh IIfx systems with (older) Farallon's StarControllers similar to the problem with Apple IIGS systems on networks with StarControllers?

Do you have the date that StarControllers began shipping with the new PAL, and what is Farallon's policy regarding upgrading old controllers?

This article has been archived and is no longer updated by Apple.
Farallon is aware of a performance loss when using the Macintosh IIfx and the Apple IIGS with the StarController, part number PN207. This occurs only on networks with Apple IIGS systems or Macintosh IIfx systems. Networks without these systems not experience any loss.

According to Farallon, the original StarController has been replaced with the PhoneNET StarController Series 300. The new product began shipping on April 30, 1990. Among other additions, this new version of the StarController contains the fix for the Apple IIGS and Macintosh IIfx.

For owners of the older StarController (PN207), chip upgrades (part number FX207) are available directly from Farallon. For more information, call Farallon customer service.

AppleShare PC 2.0: How to Set Zones

What is the analogous mechanism for PC users to change the zone they reside in? ANET? If so, which command(s)? I've gone over the manual and was unable to find the answer.

This article has been archived and is no longer updated by Apple.
ANET is the correct command to use to set the zone that you wish the PC to reside in. The exact format of the command is:

ANET USE MLIDname Z zonename

where MLIDname is the name of the MLID you are using, and zonename is the zone you wish to reside in. Executing this command also stores these values in the NET.CFG file, keeping them across restarts of the machine. For more information on this command, check page 132 of the "AppleShare PC User's Guide."

MacDFT v1.1: Doesn‘t Support IBM Entry Assist Function

Turning Document mode on enable's IBM's Entry Assist function. This feature works with several IBM host editors to provide limited local-formatting, entry, and edit control.

The key sequence that initiates this on a 3278 Model 2 terminal is "Alt-Blank" (on the MacDFT keyboard layout this is "Alt-CR POS"). Also, I have seen this function implemented on a PS/2 Model 60 using IRMA DFT.

I need to know if I can imitiate this function. However, I cannot get into Document mode, because I am already showing "Alt-CR POS" in the key position that produces this function on a 3278 terminal.

This article has been archived and is no longer updated by Apple.

MacDFT 1.1 does not support IBM's Entry Assist function. If this functionality is needed, we suggest investigating DCA's MacIrma product, because it is likely to provide features similar to those found in their DOS products.

LaserWriter: Direct Printing over Mixed Ethernet

I have a Novell Ethernet network (spread over four floors) with 30 IBM PCs. I want to connect 20 Macintosh IIs. To date, I have tested two Macintosh directly connected to the Ethernet network (version 2.15c, Mac VAP 1.1). Both of the connected Macintoshes have InterLAN NIA310 MacConnect cards running the NIA310 driver, Rev. AA, version 1.0.

I would like to connect my LaserWriters to the Macintoshes and not to the Novell Server, because the Server is on another floor. I need a solution that lets Macintosh users connect directly to Ethernet and print to any LaserWriter linked through any Macintosh II AppleTalk printer port--without requiring the user to disconnect from Ethernet and connect to AppleTalk.

1) Can I use an Apple Internet Router?

2) If yes, can I use the InterLAN card, or do I need the EtherTalk NB Card?

3) Can I use, for example, the GatorBox or FastPath as another solution?

This article has been archived and is no longer updated by Apple.
Netware for Macintosh (which is included with ELS Netware Level II 2.15, Advanced Netware 2.15, and SFT Netware 2.15) lets DOS, OS/2, and Macintosh users share Apple LaserWriters and Apple ImageWriters. Macintosh users have the option of printing directly to the printer or through the Netware print queue.

Because as Apple LaserWriters and Apple ImageWriters can be connected to the network only through their built-in LocalTalk connectors, you must use one of the routers that supports connections between LocalTalk- and EtherTalk-based networks. The Apple Internet Router, the GatorBox, or the FastPath can be used for this purpose.

You should be able to use the same InterLAN cards, if you can successfully connect to the Netware server over EtherTalk with these cards.

TA44092_ImageWriter_IIL_What_Is_It_(TIL05947).pdf

ImageWriter II/L: What Is It?

I've seen references to an "ImageWriter II/L." What is it?

This article has been archived and is no longer updated by Apple.
Apple has rolled out a new ImageWriter II printer without changing the printer's name. The easiest way to identify the new model is by observing where the serial or power connector is located. If the connector is on the leg of the printer, you have an old ImageWriter II. Otherwise, it is the recent model.

Service addressed the identification problem by using the suffix "/L" in all their service documents referring to the new printer. Articles in the Tech Info Library follow this same convention.

Parallel Interface Card: Initializing with POKEs (11/96)

This article explains how to use POKEs to control the Parallel Interface card.

This article has been archived and is no longer updated by Apple.

Neither PR# nor IN# commands in Applesoft and Integer Basic initialize the Parallel Interface. This situation can cause problems if you need to modify the parameters of the interface for your application.

The ROM on the Parallel Interface card, upon receiving the first character, sets all parameters to their default settings. After you POKE the parameter you want, the first character you send causes the ROM to overwrite all the parameter locations you have set up.

To correct this, send a character through the card and then change the parameter locations by means of the following POKEs. (Please refer to the Parallel Interface Card manual for additional information about what each POKE does.)

Replace all occurrences of "s" in the BASIC program below with the number of the slot the Parallel Interface Card is plugged into.

```
10 POKE 1400+s,80 carriage width
20 POKE 1656+s,0 character counter
30 POKE 1784+s,137 set command prefix to CTRL-I
40 POKE 1912+s,0 no video, no linefeed
or ,1 no video, enable linefeed
or ,128 enable video, no linefeed
or ,129 enable video, enable linefeed
```

The next list of POKEs replace the PR# and IN# commands and they must be used to benefit from the previous POKEs. Use "Call 1002" to execute DOS commands while the interface is enabled. However, if speed is of the essence, use the "Call 1002" after the data transfer has been made since DOS slows down I/O. All of these POKEs must be on one command line separated by colons to work in command mode; in a program, they may have separate line numbers.

```
50 POKE 54,2 PR#s
60 POKE 55,192+s
70 Call 1002
```

The normal way to reset the I/O back to the Apple video and keyboard is:

```
900 D$ = CHR$ (4): Rem CTRL-D
910 Print D$;"PR#0"
920 Print D$;"IN#0"
```

This only works after a Print and it is ignored after a Get or Print terminated with a comma or semicolon.

To avoid entering an extra Print statement, you can use the following:

```
900 Call -375 : Rem this is IN#0
910 Call -365 : Rem this is PR#0
920 Call 1002 : Rem this reconnects DOS
```

Tthe Parallel Printer Interface Card can echo characters to the Apple's video output, disable the video out while printing lines more that 40 characters long. Please refer to the Parallal Printer Interface manual for more information on what each POKE does.

AppleTalk for VMS 2.1: Running On A VAX Cluster

I want to run AppleTalk for VMS 2.1 on a VAX cluster, which has two VAX systems sharing the same disks. I cannot run AppleTalk for VMS on both VAX systems. A file called PORTDESC.TEXT can have only one AppleTalk network number and can be accessed only from a directory called ATK$ROOT. Therefore, I can run AppleTalk for VMS from only one VAX at the time.

Is this a known issue?
This article has been archived and is no longer updated by Apple.
PORTDESC.TEXT resides in the directory ATK$ROOT:[APPLETALK]. This port descriptor file is a text file that stores port descriptions. When the router process is initialized, it uses the port descriptor file to set up the port handlers. The AppleTalk for VMS installation procedure creates this file for you, using the information you supply during the installation procedure.

ATK$ROOT is a VMS logical name. You can assign it to any rooted directory. The default is SYS$SPECIFIC:.

In a cluster environment, there is a common disk that stores the entire directory structure (the common root plus each node's local root). Each local root contains, in addition to the usual system directories, a [SYSx.SYSCOMMON] directory that is an alias for [VMS$COMMON], the cluster common root directory, in which cluster common files actually reside. The disk Master File Directory (MFD) contains the local roots (SYS0 for NODE1, SYS1 for NODE2, and so on) and the cluster common root directory, [VMS$COMMON].

The VMS Install Utility puts everything in SYS$COMMON unless you specify a directory for the files. In AppleTalk for VMS installation, you have a choice for the directory ATK$ROOT. ATK$ROOT is a system-wide logical name assigned to a rooted directory. The default rooted directory is SYS$SPECIFIC:. If you install AppleTalk for VMS on each node and use the default rooted directory, most AppleTalk for VMS files are placed in ATK$ROOT:[APPLETALK] and its subdirectories. In a cluster, SYS$SPECIFIC for each node is unique. Therefore, the PORTDESC.TEXT and other files are in the unique directories for each node. Keep in mind that you must have a unique network number for each ATKVLAP port on each node, and the ATKAELAP ports on all nodes should have the same network number. That means that the PORTDESC.TEXT files are not the same on every node.

If you use the default SYS$SPECIFIC for the default during the installation and have correct network numbers in the PORTDESC.TEXT file (like above), each VAX should read the correct file when you start AppleTalk for VMS.

The only problem with this, beside the PORTDESC.TEXT file (which you want to keep unique on each VAX), is that copies of all other files are kept on each node. This can be a waste of space, and it is difficult to manage the same copies of files on each node, especially on a cluster with many nodes. If you are concerned about this, install everything in SYS$COMMON. Then, after installation, manually move the PORTDESC.TEXT file to each node SYS$SPECIFIC:. Modify the PORTDESC.TEXT files to have unique VLAP network numbers.

Re-define the ATK$ROOT logical name to search the node SYS$SPECIFIC first, then SYS$COMMON. When you start AppleTalk for VMS on each node, the cluster will search SYS$SPECIFIC and find the PORTDESC.TEXT file for that node, and then it will go to SYS$COMMON for the rest of the file.

Printing to PostScript Printer Using Novell Server (7/93)

I have a Macintosh Plus with system software 6.0.4 and 1MB RAM, connected via thin Ethernet (Nuvotech's SCSI Ethernet Device) to a Novell file server running 2.15c.

This Macintosh can access the file server without problems, but when it tries to print to a PostScript printer connected to the serial port on the file server, a NEC LC890, nothing prints -- the Macintosh can see the print queue, can go ahead and print to it, and the light blinks on the printer...but nothing happens.

Do you have any suggestions?

This article has been archived and is no longer updated by Apple.
We contacted Novell Technical Support and they confirmed that the printer device has to be one of the Apple LaserWriters or Apple ImageWriters supported by Netware for Macintosh, OR a third-party printer which supports LocalTalk and the Apple printer dictionary.

The printers have to be on the LocalTalk network connected to the Novell server via a LocalTalk Adapter such as NL1000, or on any LocalTalk networks connected to an Ethernet network connected to the server via a LocalTalk-Ethernet router.

AppleTalk Phase 2: Obtaining Node Number on Startup

Under the AppleTalk Phase 2 protocol specification, a node remembers the node number previously assigned to it and that it is stored in the Macintosh. Does the Macintosh also remember the last network number it was associated with, and where is that number stored? If the network number is not stored, does the resolution begin at the base of the network range?

This article has been archived and is no longer updated by Apple.
This information is on page 8 of the "AppleTalk Phase 2 Protocol Specification":

Obtaining a provisional address

Obtaining a provisional address upon startup is accomplished in two different ways depending on whether the node has previously saved an address in parameter RAM. An address saved in PRAM consists of two parts: the 16-bit network number, denoted $nnnn, and the 8-bit node ID, denote $yy. The concatenated 24-bit address value of [network number, node ID] is denoted $nnnnyy.

If no address was previously saved in PRAM:

Upon starting up when no information is saved in parameter RAM, a node will randomly select a provisional network number $FFnn in the startup range. This range is specified to be $FF00 to $FFFE inclusive (most significant byte first). The node then also randomly selects a node ID $yy (yy cannot be $00, $FE, $FF). As in AppleTalk Phase 1, the node must first use AARP to ensure that $FFnnyy is not in use by any other node on the network. If another node is already using this address, the node should try all other possibilities for $FFnnyy until a valid provisional address is obtained.

If an address was saved in PRAM:

If there is a saved 24-bit address of the form $nnnnyy in PRAM, the node can use it as the provisional address. The node must use AARP to ensure that this address is not in use by any other node. If another node is already using this address, the node should try all other possibilities for yy (yy cannot be $00, $FE, $FF) keeping nnnn the same until all possibilities are exhausted (nnnn is probably a valid network number for this network unless the node has been moved from another network).

If all possibilities are exhausted, the node must select a new address as if none was previously saved in PRAM (as described in the previous section).

Macintosh IIfx: Hangs with Macintosh IIci AppleShare Server

I'm having a problem keeping a new Macintosh IIfx logged on to an AppleShare 2.0 File Server running on a Macintosh IIci over LocalTalk.

Apparently, whenever the Macintosh IIfx logs on to the server it freezes and locks up. When it isn't logged on to AppleShare, the Macintosh IIfx is fine. Also, the Macintosh IIfx can log on to other non-Macintosh IIci servers without freezing.

I'm running system software 6.0.5 on the Macintosh IIfx and version 2.0 of AppleShare on the Macintosh IIci. Other Macintosh II and Macintosh SE systems run fine. I haven't tried the Macintosh IIfx serial INIT yet, nor have I tried server connections over EtherTalk or TokenTalk.

Do you have any ideas on what I might do to isolate this problem? All non-Apple INITs have been removed from the Macintosh IIfx, and there are no known viruses.

This article has been archived and is no longer updated by Apple.
We haven't encountered any problems during our testing of a Macintosh IIfx client on a Macintosh IIci AppleShare File Server over LocalTalk.

We tested the Macintosh IIfx both in the "compatibility" and "faster" modes. We wrote a program to run on the client Macintosh IIfx to write 512 bytes at a time to a file until it grew to 3MB, then erase the file and repeat the process. These specific tests ran over 24 hours. We also ran other tests over EtherTalk while investigating another unrelated issue, and the Macintosh IIfx client didn't hang during any of these tests.

Troubleshooting

- Have you tried running the Macintosh IIfx with the IOPs turned off/on?

- Do other Macintosh IIfx systems have the same problem?

- Are you using a clean system? (Did you trash the System Folder and reinstall?)

- Have you tried connecting other Macintoshes to the network connector that the Macintosh IIfx was connected to?

- Does the Macintosh IIfx in question have problems when connected to other physical networks?

- Are the other Macintosh systems used similarly; that is, are they connected to AppleShare for the same length of time, are they running the same software?

Another line of inquiry:

Is your Macintosh IIfx attached to a Farallon "Black Beauty" Star Controller or a Nuvotech TurboStar? Farallon and Nuvotech have acknowledged severe performance problems with the Macintosh IIfx over LocalTalk on their star repeaters.

Both Farallon and Nuvotech are shipping upgrades to fix compatibility problems with the Macintosh IIfx and the Apple IIGS. These systems exhibit extremely slow network response, sometimes to the point that they seem to hang, when using those network products. This may explain your

problem.

Nuvotech's upgrade to their TurboStar involves exchanging the old connector for a new one. Arrange an upgrade by contacting Nuvotech. All new TurboStars shipped since approximately the middle of June 1990 have the upgraded components and can be identified by the rev number ECO #4 on the circuit board. This newer connector also fixes previous compatibility problems with ImageWriters having and using the LocalTalk Expansion Cards and with PCs using LocalTalk PC Cards.

Farallon's upgrade involves installing a new chip in the "Black Beauty" Star Controller (part #207--easily identified since the case is black). The new platinum-colored Star Controller (part number 307) contains the fix.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

A/UX 2.0: How To Stop "newconfig" From Dumping Modules

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I have a problem with newconfig.

It seems that newconfig does not do an "eupdate" after building a new kernel. Therefore, when the system starts up and finds something strange, it takes the old kernel back from Eschatology. This leads to strange problems, like missing modules in the kernel.

Is it possible to include an eupdate in the script so the Eschatology information is automatically updated after a new kernel build?

This article has been archived and is no longer updated by Apple.

You are correct in stating that newconfig does not do an eupdate. However, we do not think that is the cause of your problem.

When the system is started up, and something "strange" is found (such as a new card installed), newconfig is run to rebuild the kernel. The file, /newunix, is used as the base for the new kernel. Since this is a minimal kernel, modules that you had previously installed will be missing.

It should be possible to write your own script that first called newconfig and then eupdate to save the new kernel in the Eschatology partition. When the system finds an invalid kernel and builds a new one, you could then restore your kernel from Eschatology.

Another method that many people use is to copy /newunix to /newunix.save and install the modules you want in /newunix. Then, anytime your kernel is rebuilt from this /newunix, you will automatically have all of the modules you want.

A/UX: Only AppleTalk Phase 2 Is Supported (9/94)

Using A/UX 2.0 and AppleTalk, it seems that we can run only EtherTalk Phase 2. Is there a way to switch back to EtherTalk Phase 1?

This article has been archived and is no longer updated by Apple.
AppleTalk Phase 2 is the only version of AppleTalk supported under A/UX 2.0 and 3.0. There are no plans to provide Phase 1 support in the future. If AppleTalk Phase 1 is required, you must use LocalTalk or, for EtherTalk, use an AppleTalk Internet Router.

AppleTalk Phase 2 is our networking system, and Apple will not continue to support two different protocol stacks.

This has already been implemented in other products, such as TokenTalk and DEC PATHWORKS (formerly LanWORKS) for Macintosh, which support only AppleTalk Phase 2.

MacX: Rootless Windows vs. Rooted Windows

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

I'm very interested in using MacX to provide nationwide access to a database I'm working on. The software is written for X Window System and (mostly) works using MacX.

I would like to have the Macintosh handle the scrolling of an image that is larger than the window. Ideally, it would be a "rootless" window. If this is possible, I can ship a complete image across the country to a user and still have the user get "excellent" response to scrolling operations. If the program on the "client" side has to do the scrolling, performance will not be acceptable.

Can you help?

This article has been archived and is no longer updated by Apple.
The only way to do what you want is to use a rooted window in MacX. If you use a rootless window, the client application will be completely responsible for all scrolling, updating, and so on. At that point, the X Window System calls are being mapped onto the Macintosh's Window Manager by MacX, and everything is being handled remotely. This includes using the scroll bars, moving the window, sizing the window, and so on.

If you use a rooted window instead, MacX will handle the bitmap, including the updating and scrolling of images that are bigger than the Macintosh window they are being displayed in.

In this case, the Macintosh window has nothing to do with the X Window System Window Manager being used. Therefore, as long as the entire X Window System image has been drawn in the Macintosh window's GrafPort, MacX will handle the scrolling and upating locally.

A/UX 2.0: MacTCP and "native TCP/IP"

Does MacTCP use the A/UX 2.0 "native TCP/IP"?

This article has been archived and is no longer updated by Apple.

Under A/UX 2.0, MacTCP maps its calls to the "native TCP/IP" calls available under A/UX.

MacTCP maintains the same API in both A/UX and the Macintosh OS, but under A/UX, MacTCP is merely a front end to the existing implementation of TCP/IP.

Excel: Leading Space Will Enter Numeric String as Text

When I enter certain text strings into Microsoft Excel, such as 2/5/80, the cell format is automatically changed to a date format. How do I avoid this without encapsulating the text in quotation marks?

In other words, how do I get Excel to treat certain text as text and not numerals?

This article has been archived and is no longer updated by Apple.
To enter a numeric string in Excel as text, type a space before the entry.

Typing " 1/1/90" (without the quotes) into a cell formatted for "d/mmm/yy" displays 1/1/90 instead of 1-Jan-90.

HyperCard: How To Use for Text File Column Alignment

I want to upload a Macintosh spreadsheet to an AS/400 - via a KMW box - as a text file with column alignment intact. Both WingZ and Excel write to text files, but add tabs between columns. I need to have spaces between columns to correctly align the columns using a nonproportional font.

I tried using Vantage/McSink, but it only left-justifies columns; I need right justification on numbers.

My idea was to get a generic TTY print driver to print the spreadsheet, then capture it to a text file for uploading. I received a TTY print driver from GDT Softworks, but can't think of a method/utility to capture printer output to a text file.

This article has been archived and is no longer updated by Apple.
We aren't aware of a commercial solution to your needs, but HyperCard can be used for a custom workaround.

Use Vantage (or Microsoft Word or equivalent) to convert the tab-delimited output from the spreadsheet to comma-delimited text. HyperCard considers each spreadsheet entry in the text file an item in a line. You could even use HyperCard to do the tab-comma conversion, but for simplicity, we'll assume the tabs have been converted.

Read the comma-delimited text into a variable (we used "container1") and call the following code:

```
on mouseUp
repeat with i = 1 to the number of lines in container1
repeat with j = 1 to the number of items in line i of container1
set cursor to busy
put expand (item j of line i of container1) after container2
end repeat
put return after container2
end repeat
open file "your filename here"
write container2 to file "your filename here"
end mouseUp

function expand which
put 25 into fieldLength
if which = empty
-- send a string of spaces fieldLength long
then
repeat with i = 1 to fieldLength
put " " after temp
return temp
end repeat
else
repeat with i = 1 to fieldLength - length (which)
put " " after temp
end repeat
-- pad with spaces
return temp & which
end if
end expand
```

The formatted text is now saved as "your filename here".

(NOTE: The entire process could have been done while reading the text in a line

at a time, rather than moving it into a container before expanding, but it was easier to explain as a multistep process.)

Display Card 8/24: RasterOps 19" 724 Is Not Supported

I need to confirm that the Macintosh Display Card 8/24 does not support the RasterOps 724 19-inch monitor.

I know that the Macintosh Display Card 8/24 GC does not support the RasterOps 19-inch monitors based on its pinouts, but there is no mention of the Macintosh Display Card 8/24.

Are the pinouts for the Macintosh Display Card 8/24 GC the same as for the Macintosh Display Card 8/24?

This article has been archived and is no longer updated by Apple.
The Macintosh Display Card 8/24 and the Macintosh Display Card 8/24 GC have the same connector and pinouts, and produce the same signals.

The RasterOps 724 19-inch monitor is not supported by either.

LaserWriter 2.0 ROM: General description of revisions (9/94)

LaserWriter Revision 2 and LaserWriter Plus are enhanced versions of the original LaserWriter printer. The original LaserWriter is fully described in Appendix D of the PostScript Language Reference Manual (copyright 1985, Adobe Systems, Inc., Addison-Wesley Publishing Co., ISBN 0-201-10179-3) so only the differences between the old and the new software will be described here.

This article has been archived and is no longer updated by Apple.
A LaserWriter containing the new software can be identified in several ways:

The test page printed at power on time includes the LaserWriter revision number in the lower left corner of the line graph illustration; for the new software, this revision number is '2.0'.

A revision entry in statusdict contains the integer '2' identifying the new revision of the LaserWriter software. A PostScript program can read this value.

The version entry in 'systemdict' contains the string '37.0' or '38.0', identifying the PostScript interpreter included in the new software.

The product entry in 'statusdict' contains the string 'LaserWriter' for a LaserWriter with the standard 13 fonts, or 'LaserWriter Plus' for a LaserWriter Plus with its expanded set of 35 fonts. Note that a program is better advised to determine the selection of available fonts by enumerating the FontDictionary dictionary.

The enhancements introduced in the new software fall into three categories, LaserWriter-specific functions, improvements in software implementation, and PostScript language changes.

1. LaserWriter-specific functional changes. There include expanded communications options, additional paper tray selections, new fonts, and various other features present in revision 2 LaserWriter and not necessarily present in other PostScript printers.

2. Improvements in implementation. Nearly all the problems present in the original LaserWriter software have been corrected, and a number of operations have been made significantly faster.

3. PostScript language changes. Several new operations and capabilities have been introduced into the standard PostScript language and are being incorporated into all PostScript printers.

Installation of the new LaserWriter or LaserWriter Plus ROM software in an existing LaserWriter causes the page count to be reset to zero and all system parameters to revert to their default values.

Apple Products: EMI Susceptibility

I am designing office workspaces to house computers and would like specifications for Apple equipment regarding acceptable electro magnetic environmental conditions.

For instance, what's the maximum 60Hz magnetic field Apple monitors can be exposed to before they produce objectionable jitter? Do you have any information about exposing disk drives to Elecro-Magnetic Interference (EMI) fields, and so on?

In addition, I would like similar information on AC power supply specifications.
This article has been archived and is no longer updated by Apple.
Except for disk drives, Apple does not perform EMI susceptibility tests on its products.

We test the disk drives to ensure that they have sufficient shielding to maintain data integrity in a typical home or office environment. As long as the drives remain in their housings, you should have a great deal of latitude when positioning them, even without adding additional shielding. They should certainly be fine in any normal home or work environment.

As a general rule, in the abnormal situation where EMI is present, your monitors will be visibly effected long before there is any affect to data on your disk drives or other hardware.

Macintosh Portable: VHF Emission Level Information

Do you have any information on the VHF interference that the Macintosh Portable generates?

This article has been archived and is no longer updated by Apple.
Apple doesn't publish the VHF levels of the Macintosh Portable, or of other systems or peripherals, which is probably why you didn't locate that information. Ironically, the Federal Communications Commission results ARE available to the public, and can be obtained from them.

The Macintosh Portable (as well as most other products we sell) is designed to be used in a home or work environment, and has been tested to comply with the limits set for an FCC Class B computing device or equivalent in all countries it is sold in. This means that it is less "noisy" or likely to cause interference than a Class A device, which can legally be used only in a work environment.

Page X of the Macintosh Portable Owner's Guide lists some measures that minimize or eliminate the Macintosh Portable's potential for radio-frequency energy interference with other electronic devices, such as radios and televisions.

AppleShare Print Server: Improving Lino L300 Spooling Speed

I ran into a severe slowdown using the AppleShare Print Server and LaserWriter Driver 5.2. on a dedicated Macintosh SE (with 2.5MB of RAM) that was spooling to a Linotronic L300. 700K files took up to 7 minutes to spool.

I then took the two high-end output workstations and linked them to the Rip 4s via Ethernet, using the 5.2 Laser Prep and so on. The same print job now took 1 minute 40 seconds to the Print Server, and 1 minute 30 seconds direct to the Rip.
This article has been archived and is no longer updated by Apple.
The Laser Prep and LaserWriter Driver 6.0 are the only drivers that are able to take advantage of font caching.

We installed LaserWriter Driver 6.0 on an AppleShare Print Server and workstations. The AppleShare Print Server then printed in 40 seconds.

Pascal: Linking from PILOT

Use the LP (LINK TO PASCAL) command to exit PILOT and enter Pascal. If you are in a PILOT lesson and wish to use a Pascal program, insert the following command into your lesson.
This article has been archived and is no longer updated by Apple.
For this example, the Pascal program is named MyProg.code.

```
LP:MyProg
```

Don't enter the ".code" suffix on the file name, since PILOT automatically adds it.

Use Pascal version 1.0 to compile your Pascal program, but link it to the system.library file provided on the PILOT Lesson1: Student Diskette. The "*$U name *" compiler option allows you to do this.

After executing the LP command, the PILOT interpreter no longer has control. LP closes any open PILOT data files, and errases from memory the status and locations of PILOT variables.

When the Pascal program ends, the system reboots your PILOT "Hello" lesson. To return to a specific spot in your PILOT lesson, have your PILOT program "leave a trail". The following example instructs PILOT to return to the label "bolts" in the lesson "Mechanics":

```
D:N$(50)
T:going off to Pascal...

R:Open file "restart"
C:N$="restart"
FOX:1,N$

R:leave a trail in the form of the
R:appropriate L: command
C:N$="L:Mechnaics,bolts"
FO:1,N$

R go off to Pascal file MyProg.code
LP:MyProg
```

The Hello lesson on the PILOT disk looks for the restart file, as follows:

```
D:N$(50)
C:N$="restart"
FIX:1,N$

R: If error flag is raised, the restart file
R: does not exist, so link to the normal first lesson

LE:firstlesson

R: Otherwise, read in the record containing our
R: restart lesson and label, and link there.

FI:1,N$
XI:N$
```

LaserWriter IINTX: Can‘t Print HPGL Files Without Translation

There are no Macintosh systems involved in this.

HPGL (a Hewlett-Packard protocol), and my LaserWriter IINTX can emulate an HP LaserJet Plus.

Therefore, if you connect our LaserWriter IINTX to a PC through the serial port, can you print HPGL format? (I don't want to convert the file before printing.)

Is it up to the program I'm using to emulate an HP plotter on an Apple LaserWriter?

This article has been archived and is no longer updated by Apple.
Briefly, the LaserWriter IINTX emulates an HP LaserJet Plus. LaserJets use PCL, not HPGL; a PC printing an HPGL print job cannot print to a LaserWriter IINTX.

Hewlett-Packard uses different printer control languages -- including HPGL and PCL -- for their different printers. HPGL is commonly used by CAD/CAM type programs for outputting to plotters; PCL is used by more common, generic programs for outputting to HP LaserJets and similar printers.

Apple's PostScript LaserWriters emulate Diablo 630s. In addition, the LaserWriter IINTX emulates an HP LaserJet Plus; therefore, a program that uses PCL and is LaserJet Plus compatible can print to the LaserWriter IINTX when the LaserWriter IINTX is in its LaserJet Plus emulation mode. Again, you cannot print an HPGL print file directly (without file translation) on the LaserWriter IINTX.

If you want to print to an Apple LaserWriter, you must use a program that supports a Diablo 630, LaserJet Plus, or PostScript-compatible printer. If your program and drivers do not support these types of printers, you need to export and, possibly, translate the data before importing the data to a program that does -- whether that program runs on a PC, Macintosh, or another system.

Published Date: Feb 18, 2012

LaserWriter IINTX: How To Print HPGL Files from a PC

Is it possible to write HPGL files from a PC to a Macintosh LaserWriter IINTX without converting them to PICT or PostScript?

This article has been archived and is no longer updated by Apple.
Two possibilities that might work are:

1) PlotView (formerly called MacHP) from Stevens Creek Software allows you to open and display Macintosh HPGL files on a Macintosh, and copy and paste them into other Macintosh programs for embellishment before printing to a LaserWriter. If you can use Apple File Exchange or a similar program and perform a generic text translation on the PC HPGL file, you can then open it with PlotView. This may work, but may require a little experimentation and manipulation with ResEdit or similar programs. Another option is to write your own AFE translator.

2) Another program that may work is called CADMOVER from Kandu, which is a 2-D/3-D Macintosh-based vector graphics translation utility, with bidirectional IGES, DXF, PICT, MacDraw, Minicad+, MacConcept, HPGL, Minicad+, Dimensions, Hyperspace and Space Edit.

Both products are listed in the Tech Info Library and/or the buyer's guides on AppleLink.

We feel the easiest solution would have been to select a program on the PC that also prints to a PostScript printer or, at least, use a program that can save the file in a format (not just an HPGL print file) that can also be read by other Macintosh or PC programs that can print to a PostScript printer. There may be PC programs that open HPGL files and save in a more commonly used file format, but we aren't familiar with any.

For more information, search under: "Stevens Creek" and "Kandu"

A/UX: Ethernet Input Errors (9/94)

I seem to have a high number of input errors on two Macintosh computers running A/UX on ethernet. This number increases all the time.

For instance, today:

Mac1:

```
Name Mtu Network Address Ipkts Ierrs Opkts Oerrs Coll
---- --- ------- ------- ----- ----- ----- ----- ----
ae0 1500 nta-ring bic 2003687 2398 461618 0 0
lo0 1536 loopback-ne loop 20802 0 20802 0 0
```

Mac2:

```
Name Mtu Network Address Ipkts Ierrs Opkts Oerrs Coll
---- --- ------- ------- ----- ----- ----- ----- ----
ae0 1500 nta-ring cm 2126045 2350 547482 0 0
lo0 1536 loopback-ne loop 18989 0 18989 0 0
```

Is this normal, or do we have a problem?

This article has been archived and is no longer updated by Apple.
The following input errors are reported as "Ierrs" by netstat:

- receive CRC errors

- frame alignment errors

- fifo overflows

- missed packet errors

One or all of these errors could be causing netstat to report the Ierrs. Unfortunately, all of these errors are summed together to create a global input error counter for each interface. This counter is what netstat is reporting to you.

As you probably already guessed, there is no program to separate the error counters for each type of input error. Without such a tool, we have little idea of what is causing the problem.

You are seeing about a 1% hit on inbound traffic. This is fairly high, but not necessarily a cause for alarm. Higher-level protocols usually take care of problems encountered in any lower layers. The problem won't be seen or felt by the user unless it is a serious enough problem to cause degradation or loss of services. You should monitor this situation, but until you can determine exactly what errors are being reported, all we can do is guess at what the problem might be.

If it's only the A/UX systems that are experiencing these errors, you can probably eliminate the physical network as the problem. Since this is a very busy network, you're probably seeing a few missed packets, and there are probably a fair amount of collisions on this Ethernet, which we suspect are frame alignment errors on the receive. All of these, with an occasional CRC error, could cause the number of errors you're seeing. It really depends on the environment and amount of traffic on the Ethernet as to how many errors will be reported as input errors.

A/UX 2.0: Problem Running rez (9/94)

I am having a problem trying to run rez under A/UX 2.0. I am using the same rez line from a makefile that runs perfectly under A/UX 1.1.

The line under A/UX 1.1 is:

/mac/bin/rez -i /cardinal/cape/HEADER/v4r8m0 -o %test test.r cursor.r

Under A/UX 2.0 Golden, I tried the following:

When using launch, I tried the following commands:

==>> ops_test.pechner /cardinal/cape/APPL/v4r8m0> /mac/bin/launch /mac/bin/rez
-i /:cardinal:cape:HEADER:v4r8m0 -s /:cardinal:cape:HEADER:v4r8m0
-o %test test.r cursor.r

==>>ops_test.pechner /cardinal/cape/APPL/v4r8m0> /mac/bin/launch /mac/bin/rez
-i /cardinal/cape/HEADER/v4r8m0 -s /cardinal/cape/HEADER/v4r8m0
-o %test test.r cursor.r

==>>ops_test.pechner /cardinal/cape/APPL/v4r8m0> /mac/bin/launch /mac/bin/rez
-i /cardinal/cape/HEADER/v4r8m0 -s /cardinal/cape/HEADER/v4r8m0
test.r cursor.r -o %test

==>>ops_test.pechner /cardinal/cape/APPL/v4r8m0> /mac/bin/launch /mac/bin/rez
-o %test test.r cursor.r

These give the following results:

/mac/bin/rez - OS error -43 (Error message file not available)
during open of "%test".
/mac/bin/rez - Fatal error trying to open the resource file "%test"
for writing.
/mac/bin/rez - Fatal Error, can't recover.
/mac/bin/rez - Since errors occured, Ttest's resource fork was not
written.

Without using launch:

==> /mac/bin/rez
-i /cardinal/cape/HEADER/v4r8m0 -s /cardinal/cape/HEADER/v4r8m0
-o %test test.r cursor.r

I get the following result:

/cardinal/cape/APPL/v4r8m0: No such file or directory
ops_test.pechner /cardinal/cape/APPL/v4r8m0>

What has worked is when I output to the default rez.out and when I specify the full pathname in test.r "#include".

Therefore, rez is not recognizing the options "-i" and "-o". It also must be "launched" to run.

Can you explain?

This article has been archived and is no longer updated by Apple.

The man page (the manual command) for rez(1) states that you must be in 32-bit mode and run the command from the command line (without using launch). You didn't specify the environment you were in when you were trying to run this.

The -o option to rez seems to work fine as long as you don't specify an output filename with a % appended to it. Rez is supposed to take the name you gave it from the -o option and affixes a % sign to it.

The -s option to rez also seems to be broken, but the -i option (which basically does the same thing) does work correctly.

Otherwise, this problem is currently (as of August, 1990) without a solution.

Apple Software Licensing Group: How to Contact

I understand Apple has a software licensing group. How do I get in contact with them and what is their function?
This article has been archived and is no longer updated by Apple.
Contact Apple's Software Licensing department for a complete list of Apple software available for licensing. This list provides information on the different types of agreements available and the corresponding license fees.

Before producing any written materials that accompany a product being licensed (such as manuals and disk labels), be sure to contact Software Licensing.

All requests to license Apple source code require a written proposal.

You can contact the software licensing group by eMail at SW.LICENSE@apple.com; by telephone at (512) 919-2645; and by fax at (512) 919-2120.

System Software 6.0.5 and System Heap Size Adjustment (11/94)

I have heard that when you upgrade to System Software 6.0.5, you should also increase your system heap size at least 32K via SUM Tools or Heap Fixer. This is supposed to increase compatibility with third-party programs.

Is this correct? If yes, what utility do you suggest?

This article has been archived and is no longer updated by Apple.
In our testing, System Software 6.0.5 does NOT require the system heap size to be adjusted to work properly with Apple or third-party software.

It is possible to run out of system heap space when using a lot of public domain or commercial INITs. This may necessitate adjusting the system heap size. We cannot make a recommendation on what utility to use, but both Heap Fixer from CE Software and SUM Tools from Symantec seem to work fine.

For more information, search under: "CE Software" and "Symantec"

PILOT: Controlling Memory Mapped I/O

Many Apple II-compatible I/O devices are memory mapped; therefore, you can control them using Apple PILOT. The PILOT system variable %M is actually a memory map controlled by a subscript. The value of this subscript defines the location in the I/O device control space addressed by %M.

This article has been archived and is no longer updated by Apple.

The I/O locations begin with address C080 (hex). This constant offset is added automatically to all %M locations. Variables %M(16) thru %M(127) address the device control space of slots 1 thru 7; access to slot 0 is not permitted. Variables %M(128) thru %M(1919) refer to the I/O select space of slots 1 thru 7. This space is typically used for ROM memory, but can be used in some cases for auxiliary device control information.

For example, the PILOT command: C: %M(16) = 0

POKEs a zero into I/O location 16, which is the first available byte (relative location zero) in the device select space of slot 1.

Similarly, the command: C: X = %M(20)

PEEKs into location 20 (relative location 4 in slot 1); it returns the result in variable X.

Generally variable %M may be used wherever the system variable %A is legal. It cannot be used to manipulate program memory from within PILOT lessons, but does provide some control of external devices.

The %M variable is a very powerful construct--I/O devices can be damaged by indiscriminate PEEKing and POKEing. Particularly avoid trying to manipulate any of the device controls for slot 6 where the disk controller is typically located. It is entirely possible to erase entire tracks of on your PILOT diskettes.

GS/OS: Setting the Finder as the Startup Application

My school district has an Apple IIGS network.

I want to change the startup application from Aristotle to the GS/OS 5.0.2 Finder. I tried to set "Finder" as the startup and got an error, "Unable to load descriptor $004E".

I set the appropriate permissions for access to the GS/OS operating system folder on the server, but I got the same error.

Can you help?

This article has been archived and is no longer updated by Apple.

The $004E error indicates that GS/OS attempted an invalid access procedure. There was only one way we were able to duplicate this error -- by denying access privileges to the Icons folder on the server. When the access privileges on the Icons folder weren't set to See Folders/See Files for everyone,the "Unable to load descriptors" message appeared. Descriptor refers information stored in files within the Icon folder, which is needed by the Finder. Once we reset the Icon folder privileges so See Folders/See Files were allowed for everyone, startup proceeded normally.

Once access is granted to the Icons folder on the server and Finder is set as the startup application in the server's Admin program, the startup process should continue until you reach the Finder's desktop.

IMPORTANT NOTE: When using the "Icon Info" menu item from the GS/OS "Special" menu, there is one step that is sometimes forgotten. Be sure to press the "Apply" button while on the "Access" card of the "Icon Info" dialog box after making any changes to access privileges. If this button is not pressed, the changes are not recorded and the privileges revert to the previous settings.

AppleShare PC 2.0.1: Use COMPAT.COM for Compatibility

I have a DOS machine with a LocalTalk PC Card running AppleShare PC 2.0.1, and I'm trying to run TCP/Connect through the card.

TCP/Connect was configured to run with AppleTalk; however, when running version 2.0.1 of AppleShare PC, I get an error that "AppleTalk was not initialized with the proper interrupt". TCP/Connect claims that this product worked with AppleShare PC 1.X.X, and that it uses interrupt #60.

Were the interrupts changed from version 1 to 2? If yes, what interrupt range can be used by the software?

This article has been archived and is no longer updated by Apple.
It's not surprising that a product layered on top of the protocol stack in AppleShare PC 1.X wouldn't automatically work with AppleShare PC 2.0.1. Apple totally reworked the interface to make it more accessible to developers, and we changed the way we interfaced with MS-DOS. This includes the interrupts used.

There should be a relatively simple solution to the problem.

There is a program that ships with AppleShare PC 2.0.1 that tries to ensure compatibility with programs that layered on top of older versions of AppleShare PC. This program is called COMPAT.COM. You should run it immediately after you run ATALK.COM (most likely in a batch file). It intercepts the old style calls and reroutes them to the new API.

MacX: Window Management Q & A (4/93)

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

Here are some questions and answers about MacX and window management.

This article has been archived and is no longer updated by Apple.
Q) Does the host machine send bitmaps or an object / vector description to the network? If bitmaps are a sent, there may be some issues with network performance and cutting and pasting text.

A) Typically, an X client application sends information in the form of an object / vector description. For instance, when drawing a scroll bar, the bit image of the scroll bar is not transmitted, only the commands to generate the bit image are transmitted. However, it is quite possible for the client application to transmit bit images. A perfect example of this is a bit image viewing application.

Q) Does MacX always use the Macintosh Window Manager in rootless and rooted modes? I'm running Open Look under MacX in a rooted window, and I'm concerned about the implications of the Open Look interface being mapped onto Macintosh windows (although I can understand why this may have been done). I'm concerned also with consistency between machines. I have had some interesting problems with windows disappearing, use of menus, and so on (things that may be considered normal with the Macintosh interface). Interestingly, the calculator appears in a normal Open Look window, but everything else is in Macintosh windows. My feeling is that the choice of rooted or rootless should define what happens (that is, whether Macintosh windows or Open Look windows are used).

A good example of the problem is when you iconify the clock. Normally, under Open Look, the time still appears and is updated--in MacX this doesn't happen. Is there a way that this can be configured to use Open Look windows (I am aware of the disadvantages), or will Macintosh windows always be used?

A) When you execute a client application in a rootless window, MacX always maps the client's calls into the Macintosh Window Manager. When you use a rooted window, the Macintosh Window Manager is not used except to contain the entire "screen" or display that is being drawn into. If client applications are being displayed in Macintosh windows, the environment for the remote call is not being properly set. You need to set the display to the rooted window desired for each application you execute.

TA44131_K_Disk_Eject_INIT_Not_Available_for_the_Apple_IIGS__(TIL05995).pdf

800K Disk Eject INIT: Not Available for the Apple IIGS (11/94)

I use the 800K Eject INIT in Macintosh systems. Is there is a similar program for the Apple IIGS?

This article has been archived and is no longer updated by Apple.
There is no program for the Apple IIGS that provides the same function as the 800K Eject INIT. There were no reports of drive failures on the Apple IIGS using 800K disk drives, as there were with some Macintosh systems. Because of this, such a program is not necessary.

Pascal: How to read Apple PILOT data files

Though it may appear that data files are randomly accessible text files, they are actually block structured files, two strings long, with 255 per block. Records 0 and 1 are contained in relative block zero, 2 and 3 are in block 1, etc. The Pascal construct which defines this file format is:

VAR PILOTFILE: FILE OF STRING [255];

The data record associated with this file has the description PILOTFILE^, with a string of length 255. This file may be sequentially or randomly accessed using the commands Get, Put and Seek. See the Pascal Language Reference manual for details.

This article has been archived and is no longer updated by Apple.
To open an existing file, use the Reset command; a new data file may be created using Rewrite. These commands are the same as the PILOT commands Fix and Fox respectively. Always Close a new file using the Lock option to record the data file in the diskette directory.

PASCALPGM Links to the Pascal program contained in the file PASCALPGM.code. Compile any intrinsic library units this program requires with the libraries found on your Apple PILOT Author Diskette or Lesson Diskette using the Pascal 1.0 compiler. The Apple PILOT system uses a special 48K run-only version of Pascal 1.0, which requires different intrinsics due to its unique storage allocation.

The linkage from PILOT to Pascal is one-way: data cannot be transmitted from PILOT to Pascal, except by data files on diskette. When the Pascal program ends, the PILOT lesson diskette reboots automatically and begins executing the Hello program if any. Programs running in this environment have approximately 10K less user storage space than in the standard Pascal system.

The first compiled procedure in the outer block of any Pascal program running under the PILOT system should be:

```
Procedure Syserror;
Begin
End;
```

System errors automatically divert control to this procedure, with IOResult set to the corresponding error number. The default action is:

A. If the error is non-fatal, execution of the procedure currently executed is aborted. Execution of its calling procedure is resumed.

B. When the error is fatal, the program terminates with an appropriate error message. Any additional error checking or recovery should be done in this procedure.

The following example prints the contents of any Apple PILOT data file:

```
Program Datalist;

Var PILOTFILE: file of string [255];
Filename: string;
RECNO: integer;

Procedure Syserror;
Begin
End;

Procedure Pause;
Begin
Writeln;
Write ('Press RETURN to continue...');
Readln;
Writeln
End;

Begin
Page (output);
Write ('List which data file? ');
Readln (Filename);
Writeln;
Filename := CONCAT (Filename,'.data');
RESET (PILOTFILE, Filename);
RECNO := 0;
```

```
While not EOF (PILOTFILE) Do Begin
Writeln ('Record ',RECNO,': ',PILOTFILE^);
Get (PILOTFILE);
RECNO := RECNO + 1;
If RECNO MOD 20 = 0 Then PAUSE
End;
Writeln;
Writeln ('End of file: ',RECNO,' records listed.');
Pause
End.
```

TA44135_Wang_LPSLIS_Laser_Printer_Connecting_to_a_Macintosh_(TIL06000).pdf

Wang LPS/LIS-8 Laser Printer: Connecting to a Macintosh

Can I connect my Macintosh systems to a Wang LPS/LIS-8 laser printer? If yes, please explain how to do this.

This article has been archived and is no longer updated by Apple.
The LPS-8 printer technology is many years old and is not likely to be PostScript-compatible. Therefore, to print Macintosh files you would need a specialized driver -- and to our knowledge, none exist. Alternatively, if the printer is similar enough to other printers for which third parties like GDT provide drivers (HPs, daisy-wheel printers, and so on), you might be able to use one of those drivers along with a serial connection.

To initiate a print job when the Macintosh is emulating a Wang terminal is much more likely by using one of the terminal emulation products described in the Tech Info Library or in one of the AppleLink buyer's guides. However, we don't think this is what you are looking for, and you'd definitely lose the neat graphical and WYSISYG capabilities the Macintosh offers.

A third possibility is to translate the Macintosh file to a Wang file format to print on the LPS-8, but again you'd lose many of the advantages of the Macintosh.

Printers: Paper and Envelope Dimensions

This article lists the dimensions of the most common standard paper and envelope sizes. Consult the materials that came with your printer to determine the paper sizes and weights appropriate for it. For a complete discussion of ISO 216:1975 series paper sizes, please see Tech Info Library article number **19885**.
This article has been archived and is no longer updated by Apple.

ISO 216:1975 Standard Sizes

The following table shows the width and height of ISO A- and B-series paper formats, as well as the ISO C series envelope formats. The dimensions are in millimeters. Sizes supported by Apple LaserWriter printers are in bold text (not all printers support all sizes).

A Series Paper		B Series Paper		C Series Envelopes	
4A0	1682 x 2378	--	--	--	--
2A0	1189 x 1682	--	--	--	--
A0	841 x 1189	B0	1000 x 1414	C0	917 x 1297
A1	594 x 841	B1	707 x 1000	C1	648 x 917
A2	420 x 594	B2	500 x 707	C2	458 x 648
A3	**297 x 420**	B3	353 x 500	C3	324 x 458
A4	**210 x 297**	**B4**	**250 x 353**	C4	229 x 324
A5	**148 x 210**	**B5**	**176 x 250**	**C5**	**162 x 229**
A6	105 x 148	B6	125 x 176	C6	114 x 162
A7	74 x 105	B7	88 x 125	C7	81 x 114
A8	52 x 74	B8	62 x 88	C8	57 x 81
A9	37 x 52	B9	44 x 62	C9	40 x 57
A10	26 x 37	B10	31 x 44	C10	28 x 40

ISO standard paper and envelope sizes are not yet widely used in Canada and the United States. However, many paper manufactures and resellers carry ISO stock sizes.

Customary Sizes

The following table shows the width and height of customary paper sizes used in North America. Many, but not all, Apple LaserWriter printers can print at these sizes.

Paper Size	mm	inches
Tabloid/Ledger	279 x 432	11 x 17
US Legal	216 x 356	8.5 x 14
US Letter	216 x 279	8.5 x 11
Folio	210 x 330	8.25 x 13
Executive	184 x 267	7.25 x 10.5
Statement	140 x 216	5.5 x 8.5
Postcard	100 x 148	3.94 x 8.82

The following table shows the width and height of customary envelope sizes used in North America and Germany. Many, but not all, Apple LaserWriter printers can print at these sizes.

Envelope Size	mm	inches
DL (DIN Long)	110 x 220	4.33 x 8.67
Comm 10	105 x 241	4.13 x 9.5
Monarch	98 x 191	3.88 x 7.5

AppleShare PC 2.0.1: EtherLink II Problems

I'm using AppleShare PC 2.0.1 and the 3COM EtherLink II card (AT bus card). I'm trying to use a thick Ethernet external transceiver with the card.

Essentially, the card seems to be functioning, but it does not communicate with the network. I've also noticed that the NET.CFG file generates the same code for both thin and thick Ethernet.

Since AppleShare PC is supposed to support this card out of the box, I need some help. Do you have any suggestions?

This article has been archived and is no longer updated by Apple.
There are several potential causes for problems with AppleShare PC and 3COM EtherLink II cards.

The most common is attempting to use Phase 1 services (usually after upgrading from AppleShare PC 1.x to AppleShare PC 2.0.x). Since AppleShare PC 2.0.x is Phase 2 only, you can only use it with Phase 2 services unless a router with both Phase 1 and Phase 2 drivers is present.

The card model is also important. 3COM has produced at least three different PC or AT bus Ethernet cards, all with the name EtherLink II. We are familiar with models 501, 503, and 505. The model 501 is an 8-bit card, quite old, and not supported. The model 503 is the most common, and what we wrote our EtherLink II MLID for. The model 505 arrived later and is a 16-bit card (AT bus only). We do not yet support this card. The 503 driver will not work with it because the model 505 is substantially more complex and full-featured.

Another reason could be that they are trying to load 3COM-supplied drivers before loading AppleShare PC. This does not work. It prevents AppleShare PC from communicating with the network. Installing NetBIOS support will have the same effect.

Finally, the ENET3CII driver has problems when the bus speed of the PC is over 8MHz. The CPU speed can be greater, but the expansion bus speed cannot be above 8MHz. This is rarely a problem, but could be if you shift the PC into its non-turbo mode and things work.

Mac OS X Server 1.x: Managing Users and Groups With NetworkManager.app

NetworkManager.app is used to configure users, groups, file sharing, computers, and other services. This article explains how to use NetworkManager.app to set up users and groups.
This article has been archived and is no longer updated by Apple.
If you are unfamiliar with NetInfo domains, please see the following article:

Article 30832 "**Mac OS X Server: Basic Introduction To NetInfo Domains**."

The NetworkManager application (/System/Administration/NetworkManager.app) is used to configure computers, users, and groups in a NetInfo environment. It allows the System Administrator (root) to make changes network wide or to a specific domain. This is in contrast to other Unix-based systems where users have to be added to each computer.

Note: Changes made with the NetworkManager application require the System Administrator's (root) password for the domain being configured. This may be for the local domain (an individual computer), or it may be the root domain (the entire network of computers). Do not try to make changes to domains you do not have access to.

Selecting The Correct Domain

Note: If the computer is not part of a NetInfo network, please skip to the next section.

NetworkManager allows you to make modifications network wide, so you must select the domain you want to change. If the computer is not part of a NetInfo network, the local domain is the only one available to edit. If the computer is part of a NetInfo network, any domain you have permission to edit may be selected.

Select a domain to edit by typing its name in the field titled Domain: at the top of the frontmost NetworkManager window. To see a list of the domains available for editing, click the disclosure triangle to the left of the Domain field. Click on a domain name in the list to select it, or type its name in the Domain field.

Once the domain you wish to edit appears in the Domain field, you may add or edit computers, users, and groups of users to NetInfo using the NetworkManager application.

Before we begin, a quick word on button conventions: A button with a star is for a new item; a button with a pencil is for editing an item; buttons with the international symbol for "no" are for deleting an item; and buttons with a pencil and outline are for editing default profiles. Finally, buttons with one face are for users, and buttons with two faces are for groups.

Why Add Users?

Unlike the traditional Mac OS, Mac OS X Server is based on a Unix-compatible operating system. This creates the need for a paradigm shift for those who are familiar only with the Mac OS. Mac OS X Server is a multi-user environment. So, the operating system must have a way to identify users, and what they have access to. Mac OS X Server identifies a user with a login and password. Once identified, the user has access to the appropriate files and directories. A user is added anytime a new person needs access the system.

There are two types of users in Mac OS X Server. The first is more similar to traditional Mac OS users, because they are local. Local users exist only on one computer. They may still have access to network applications, but they do not have stored space on a server.

Network users are much more flexible. In contrast to local users, network users live on a server. Their files and programs are stored there. They generally have limited access to local files and directories. Network users are able to login to any computer that is on the NetInfo network to which they were added.

Managing Users

To add a new user open NetworkManager. Click on the Users and Group button. It is the top button on the left-hand side of the window and has the word "Users" under it.

With the Users button selected, two tabs become visible. The first is Users and the second is Groups of Users. Select the Users tab.

If the system is just being configured, there is only one user, named Nobody. More users can be seen by checking the Show System Users checkbox. **Note**: These users should not be tampered with except by an experienced administrator.

Click the new user button and the newuser window opens. It is important to fill in all of the fields. Do not change the User ID, Login Shell, and Home Directory unless necessary. **Note**: New users are able to change their passwords after their initial login by opening Preferences.app and

selecting the Security option.

At this time it is also possible to add the user to any preexisting groups by clicking the Add... button and selecting the group. The wheel group allows users to become the root user if they have the root password. This privilege should only be given to trusted users! It is also possible to add users to a group by clicking on the new group button.

Managing Groups

You manage groups by clicking on the Groups of Users tab.

Clicking on the new group button brings up the new group window. Type in the name of the new group and use the Add User button to add existing users to the group. Editing and deleting users can be done with the appropriate buttons. **Note**: Do not delete preexisting groups.

Giving Network Users Root Access

In normal network operation, most users login to their computer through their network user login. However, it is sometimes necessary to have System Administrator (root) access to the local computer. This can be accomplished by adding the network user to the local computer's wheel group. The wheel group allows users to substitute user identity--"su"--to root in a terminal window if they have the root password. This privilege should only be giving to trusted users!

The first step is to click the Groups of Users tab in the Users section of the NetworkManager. Then double-click on the group the user is to be added to, in this case wheel. In the window that opens click Add User.

Scroll through the list of users to find the user to be added, and double-click it.

Close the window, save changes and enter the root password for the domain that you are making the change to. The user now has permission to "su" to the root user for that domain. Currently, a user can only "su" to a user by using the terminal window.

Mac OS X Server 1.x: Using NetworkManager To Manage Computers In NetInfo

This article describes how edit computer entries in NetInfo for using the NetworkManager application.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you are unfamiliar with NetInfo domains, please see the following article:

Article 30832 "**Mac OS X Server: Basic Introduction To NetInfo Domains**."

The NetworkManager application (`/System/Administration/NetworkManager.app`) is used to configure computers, users and groups in a NetInfo environment. It allows the System Administrator (root) to make changes network wide, or to a specific domain. This is in contrast to other UNIX-based systems where users have to be added to each computer.

Note: Changes made with the NetworkManager application require the System Administrator's (root) password for the domain being configured. This may be for the local domain (an individual computer), or it may be the root domain (the entire network of computers). Do not try to make changes to domains you do not have access to.

Selecting The Correct Domain

NetworkManager allows you to make modifications network wide, so you must select the domain you want to change. If the computer is not part of a NetInfo network then the local domain is the only one available to edit. If the computer is part of a NetInfo network then any domain you have permission to edit may be selected.

Select a domain to edit by typing its name in the field titled "Domain:" at the top of the frontmost NetworkManager window. To see a list of the domains available for editing, click the disclosure triangle to the left of the Domain field. Click on a domain name in the list to select it, or type its name in the Domain field.

Once the domain you wish to edit appears in the "Domain" field, you may add or edit computers to NetInfo using the NetworkManager application.

Before we begin, a quick word on button conventions: if a button has a star it is for a new item, a button that has a pencil is for editing an item, buttons that have the international symbol for "no" are used to delete an item, and buttons that have a pencil and outline are to edit default profiles. Finally, buttons that have one face are for users, and buttons that have two faces are for groups.

Why Add Computers In NetworkManager?

NetworkManager is one way of adding information to a NetInfo database. Using NetworkManager it is possible to add computers to a network domain or to a local domain. If a computer is added to a network domain, it becomes part of that domain and have access to network resources. If a computer is added to a local domain, it only has access to the resources of the computer running the local domain. Adding computers to a local domain is similar to adding entries to a computer's host file.

Computers are added to a NetInfo database so that the computer can access the shared information stored in the database.

Adding computers in NetworkManager

Adding computers to NetInfo is very easy with NetworkManager. Once you have selected the domain you wish to edit, click the "Computers" button on the left-hand side of the window to begin.

As in the "Users" pane, there are buttons across the bottom of the window that allow you to create, edit, and delete computers from the NetInfo database.

To add a computer, click the button that has a computer and star on it. The first three fields must be completed, and must be unique to the network. **Note**: This article covers filling out the first three fields, but not the other fields available in this window.

The computer name and IP address are ways that the computer will be identified on the network. These are used by a variety of different protocols and applications. The hardware Ethernet address it is built into the computer. You can find out the computer's Ethernet address by opening the Preferences application (System/Applications/Preferences.app) and then opening the Network option. Once the Network option is open, click on the "Connections" tab and choose "Hardware Info" from the pop-up menu. Click on the Ethernet interface you want to use, and its hardware Ethernet address will appear on the right.

Once the Ethernet address is known it can be entered into the correct field in the NetworkManager application. **Important!** The hardware

Ethernet address is displayed with leading zeros in the Preferences application, for example: 00:08:05:bf:05:09. In order for NetInfo to correctly recognize the computer, you must enter the address without leading zeros in the NetworkManager application, for example: 0:8:5:bf:5:9.

The hardware Ethernet address is used by bootp to assign an IP address to the computer at boot, or to allow the computer to network boot from the server.

Removing Computers In NetworkManager

If a computer is no longer on the network it can be removed by selecting its name from the list of computers and clicking the Delete Computer button. You cannot undo the deletion of a computer.

Changing Computers In NetworkManager

Sometimes a user gets a new computer, or gets tired of a host name. The Edit Computer button is a simple and fast way to update computers in NetInfo. If a user has a new computer, but wants to keep the other information the same, the only entry that needs to be updated is the new computer's hardware Ethernet address. The host name can also be changed by simply entering a new one.

Mac OS X Server 1.x: Configuring the Apple Menu

Configuring the Apple menu in Mac OS X Server is similar to Mac OS 8, but it does have some new features and procedures. This article discusses customizing the Apple menu.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Configuring the Apple Menu

The Apple menu appears in the upper left-hand corner of the monitor. Anything can be placed in the Apple menu to make items easier to open. Individual users can configure their own Apple menu.

The AppleMenuOptions application is located in the following path: /System/Applications/AppleMenuOptions.app. This application is used to configure everything about the Apple menu.

When the AppleMenuOptions.app is opened, there are two tabs present at the top of the window, "Organize" and "Recents."

The Organize Tab

The Organize tab is used to configure the overall order of the items in the Apple menu. At the bottom of this panel are several buttons.

The first button is titled "Default." This button restores the Apple menu to its factory configuration.

The "New Submenu" button creates a new submenu in the Apple menu. A submenu has a folder icon with an arrow to the left of its title. When a submenu is highlighted, the items in the submenu appear to the right of the Apple menu. Items are added to a submenu by highlighting the submenu in the "Organize" tab, and then clicking the "Add Item..." button.

The "New Separator" button is used to add a line between two items that appear in the Apple menu. In the default configuration, two separators are used to isolate the Mac OS item in the Apple menu. These are useful for organizing items in the menu.

The "Add Item..." button was briefly discussed above. It can be used to add items to the main Apple menu, or to a submenu. When this button is clicked it brings up a navigation window. You add an item by browsing the filesystem and locating the item to be added to the Apple menu and double clicking on it. You may also type in the full path for the item you wish to add. Clicking "OK" will add the selected item to the Apple menu.

The "Edit Item..." button is used to edit the name, location, or icon of a previously existing item.

Items in the menu can be reordered by simply clicking on them and dragging them to the new location.

To remove a menu item, select it by clicking on it, and then click the "Remove" button.

The Recents Tab

The Recents tab can be configured to keep track of recently used applications and documents.

Under the "Show Last" field you may select how many previously used applications or documents the operating system will keep track of. The maximum number is 99.

Also on this tab is a pop up menu titled "Recent:." By choosing "Applications" or "Documents" you can see, in list view, the previously opened applications or documents. You may delete an item from this list by clicking on it and then clicking the "Remove" button.

Restoring Default Settings

The default settings for the Apple menu can be restored by clicking on the "Default" button found on the Organize tab. If this does not work, it is possible to delete the preferences file manually. To do so, you must be logged in as root. The preferences file is located in a given user's home directory in the following path: `~/.OpenStep/AppleMenu/NSAppleMenu.appleMenuDomain`. **Note**: In Mac OS X Server the ~ symbol refers to the currently logged in user's home directory.

Mac OS X Server 1.x: The Desktop and Viewer

This article describes the Desktop and Viewer as implemented in Mac OS X Server. Its purpose is to differentiate between the traditional Mac OS and Mac OS X Server. It also provides some useful keyboard shortcuts.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The Desktop

In Mac OS 8 the Desktop Folder is an invisible folder on the hard disk. Everything in that folder appears on the desktop. Dragging an item to the desktop moves it into the Desktop Folder.

In Mac OS X Server the desktop is not designed this way. If an item is dragged to the desktop, a symbolic link to the original item is created. A symbolic link is, for the most part, the same as an alias in the traditional Mac OS. Only symbolic links can reside on the desktop.

There are some things to know about symbolic links. If a symbolic link is copied from one viewer window to another, a dialog box appears. It gives you the option to create a new link in the desired location, to skip copying the link, stop copying, or to copy the original item instead of the symbolic link.

If a link is copied from the desktop, this window does not appear. The original item (to which the link is pointing) is automatically copied to the new location. This is because a symbolic link on the desktop is treated differently than symbolic links in other locations.

The Viewer

Viewing Methods

The Workspace Manager's main navigation tool is the Viewer window. There are three ways to navigate the filesystem using the Viewer. The two that are most familiar to Mac OS or Windows users are the icon view and the list view.

The icon view provides the least amount of information about a file and its directory hierarchy. It only shows an item's icon and title. Directories are shown as folders. Double clicking on an item opens it. Double clicking a directory icon opens a new Viewer window.

The list view is more informative. It provides information about the size of the item, its modification date, and the owner and group to which it belongs.

The least familiar, but perhaps best, is the column view. This viewing method can be thought of as a browser because it allows the user the see multiple directories in the same window, thus saving space. The items inside a directory are listed in columns. When you click on a directory, the Viewer is updated to display the contents of that directory. With this viewing method it is possible to see into multiple directories in one window.

Keyboard Shortcuts

Holding down the Command key while dragging an item to another directory moves it to its new location. The arrow pointer changes so that it has a box to its right.

Holding down the Option key while dragging an item to another directory copies it to its new location. The arrow pointer changes so that it has a plus sign to its right.

Holding down the Control key while dragging an item to another directory creates a symbolic link in the new location. The arrow pointer changes so that it has a curved arrow to its right.

The Tool Bar

The Tool Bar is a group of eight buttons that appear at the top of the Viewer window. The Tool Bar is shown or hidden from the View menu in Workspace Manager. For this discussion the first button on the left is numbered 1 and the last button on the right is numbered 8.

Button 1 has a picture of a house on it because it changes the directory being browsed to your home directory. Button 2 has a folder with an up arrow because it changes the directory being browsed to the one above it.

You may not be able to use to buttons 3, 4, and 5 depending on your level of permissions for a file or directory. In Mac OS X Server when a button has a star on it, the button creates a new item. In this case, button 3 (with a star and folder on it) creates a new folder in the current directory. Button 4 duplicates any selected item(s). Button 5 moves the selected item(s) to the Trash.

Button 6 allows you to choose the way a Viewer window is displayed: by icon, by list, or by columns. These view options are described above.

Button 7 allows you to type the path of the directory you want to browse without having to navigate the filesystem.

Button 8 opens up the Inspector. The Inspector is described in its own article.

The Tool Bar can be turned on or off by selecting the appropriate command from the View menu in the Workspace Manager.

Key Differences

Currently, it is not possible to copy, move, or create symbolic links in the same Viewer window. A second Viewer window must be opened, and the item to be copied, moved, or linked must be dragged to the second Viewer window.

Also, a Viewer window is not automatically updated when a change is made to the filesystem. To see any changes to the filesystem, you must select Update Viewers from the View menu or by type Command+U.

When you double click on a directory icon in icon view, a new Viewer window opens. Holding down the Option key while double clicking on a directory icon opens the directory in the same window.

Changing the name of an item is similar to the traditional Mac OS with one key difference. After selecting an item, you must click on its title. The highlight disappears and the pointer changes from an arrow to an I-Beam. After changing the name, you must press the Return key in order for the change to take effect.

A/UX 2.0: panic(vbwrite) Error

I'm having problems with A/UX 2.0 and the Macintosh IIci.

I receive VB Write Error, at which point MultiFinder freezes up. I don't have to be doing anything with my system for this to occur. The systems configuration is as follows:

Hardware

Macintosh IIci with HD80 SC and 8MB RAM
EtherTalk NB Card rev L
Apple external 160SC

Software

A/UX 2.0

This article has been archived and is no longer updated by Apple.

```
The error you're seeing is probably "panic(vbwrite)".

This is a kernel panic error which occurred in the I/O buffer routines.  The
I/O buffer routines take care of reading/writing and freeing buffers within the
UNIX kernel.  In this case the kernel thinks the size of the available buffers
are smaller than the amount of data that needs to be written out.  In other
words, you can't write out what you don't have.  This is a very serious error,
which under normal circumstances should never occur.

The first thing to resolve the problem is to try a "kconfig -v -a /UNIX >
kernel.conf" and have the output checked by an expert.

Let the same person look at a "module_dump /unix".

Mac OS X Server 1.x: Importing NFS Directories With NetworkManager

This article discusses NFS and how to import directories with NFS.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you do not already have an understanding of NetInfo domains, please read articles:

Article 60038: "**Mac OS X Server: What is NetInfo?**"
Article 30832 "**Mac OS X Server: Basic Introduction To NetInfo Domains**."

What Is NFS?

NFS stands for network filesystem. A filesystem in Mac OS X Server generally means a directory or directory hierarchy. NFS is based on the client/server model. The server exports the filesystems, and the client imports them. With NFS it is possible to seamlessly share filesystems to other computers on a network. When users changes directories, they should not know that they are now looking at a remote filesystem. This is very powerful because it allows common resources to be stored on one computer, and accessed throughout the network. This would be an excellent idea for documentation like man pages, or read me files.

Selecting The Correct Domain

NetworkManager allows you to make modifications network wide, so you must select the domain you wish to change. If the computer is not part of a NetInfo network then the local domain is the only one available. If the computer is on a NetInfo network then the domain that you have access to must be selected.

The domain is selected at the top of the NetworkManager window in the field title "Domain." To reveal the larger domain hierarchy, click the disclosure triangle to the left of "Domain." The correct domain name can be typed or selected.

Once the correct domain appears in the "Domain" field, NetworkManager can be used.

A quick word on button conventions; buttons that have a star are for a new items, buttons that have a pencil is for editing items, buttons that have the international symbol for no are to delete items, and buttons that have a pencil and outline are to edit default profiles. Finally, buttons that have one face are for users, and buttons that have two faces are for groups.

Importing Filesystems

Importing directories from a server is very similar to exporting them. Click the "File Sharing" button along the left-hand side of the window and then click the "Mounted Directories" tab. This is where filesystems are imported from other computers. Once again, it is critical to make sure that the correct domain is chosen at the top of the window.

Clicking the new directory button in this window will open a new window. In this window you specify where and how to import a filesystem.

The first field in this window specifies the server and the directory to import. If the server that is exporting the directories is in NetInfo, you can use the "Select" button to choose the server. If the server is not in NetInfo its information must be typed into the field.

example:[hostname]:/directory	www.foo.com:/web

The next field specifies where the imported directories are to be mounted on the local computer. This can be any existing directory on the local computer. This directory is called a mount point. If files or directories exist inside a mount point, these items are not accessible while a filesystem is mounted there. If the remote filesystem is unmounted then these items can be accessed.

Finally, specify the import options. The table below lists the options and describes them.

Mount this directory as read only	This option will not allow changes to the remote filesystem to be made.
Return an error if the server does not respond	If the server does not respond to the mount request an error message will be generated.
Allow interrupts	Allows a user to terminate the importing if the server is down.
Mount this directory in the background	If the mount fails, the computer will try to mount the directory in the background.

Ignore setuid	Ignore the setuid and setgid bits, which otherwise when set on executable files, will cause the program contents of the file to run as the user (and/or group) which owns the file. This option plugs a potential security hole caused by this behavior.

Once the options are set, close the window and save the changes. Two dialog boxes appear. The first requests that you enter the root password. The second tells you that the changes will not take effect until the computer is restarted.

Note: Changes made with this program require the root password to the domain you are trying to configure. This may be only for the local domain (your computer) or it may be the root domain (the entire network). You should not try to change settings you do not have access to.

Mac OS X Server: Starting Up Mac OS From A Separate Disk

This article tells how to start up a computer from a separate hard disk containing a different version of Mac OS (such as Mac OS 8.5) when the default hard disk has Mac OS X Server installed and is the default startup volume.
This article has been archived and is no longer updated by Apple.
To start up the computer in Mac OS 8.5 instead of Mac OS X Server, hold down the Option key while the computer is starting up. Mac OS 8.5 must be installed on a separate drive or partition, and that drive or partition must be selected in Mac OS 8.5's Startup Disk control panel.

Mac OS X Server 1.x: UFS Partitions Do Not Mount In Mac OS

The Mac OS X Server installer changes the partition type of the partition on which Mac OS X Server is installed. This change results in the partition not mounting in the Mac OS.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

When a user selects the drive or partition to install Mac OS X Server on to, the installer modifies the partition map so that the selected partition is no longer a Mac OS volume. The installer changes the type of partition to Apple_Rhapsody_Inst. This is the type of partition that the installer scripts recognize, thus allowing the files to be installed.

Just before Mac OS X Server is installed, the installer scripts change the partition type again. This is because Mac OS X Server is a Unix-style operating system and must be installed on a UFS drive. This time the type of partition is changed to Apple_Rhapsody_UFS.

After the installation process has successfully finished, or if it failed, the selected partition does not mount in the traditional Mac OS. This is because neither Apple_Rhapsody_Inst, or Apple_Rhapsody_UFS partition types do not mount in the Mac OS. So, these partitions are not accessible while in Mac OS.

A common example of a failed install is if the user did not boot off of the Mac OS X Server CD. The partition types are changed, so the partitions do not mount.

If the install failed, try running the installer again making sure the error is not procedural in nature. The installer can recognize both types of Apple_Rhapsody partitions, so if the partition is recognizable it sees it. The installer now lists the partition as either the "Mac OS X Server Install" partition or the "Mac OS X Server UFS partition." Select this partition and try to install again, following the procedures carefully.

If the partition that had Mac OS X Server installed successfully or unsuccessfully, it must be reformatted with Drive Setup or another formatting utility that supports HFS or HFS+ in order for it to mount in Mac OS again. It may be possible to edit the partition map with pdisk back to a Mac OS volume, but Apple does not provide support for this.

Mac OS X Server 1.x: What Is NetInfo?

This article explains the fundamentals of NetInfo. It also describes how to back the database up, and restore the database to its default state. The final part of the article is a set of links to other articles that aid in understanding how NetInfo operates.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

NetInfo is a hierarchical distributed database that is used to keep track of administrative data in NeXTSTEP, OpenStep for Mach, and Mac OS X Server. It can store information on user and group accounts, e-mail configurations, NFS (network filesystem), printers, computers and other resources. Since this information is stored in NetInfo these resources are easily configurable, and can easily be shared over in a network environment.

A NetInfo Domain is the basic unit of the NetInfo hierarchy. For a discussion of domains please see article:

Article 30832 "**Mac OS X Server: Basic Introduction To NetInfo Domains**."

NetInfo Servers

Every computer that runs NetInfo is also a NetInfo server. This is because every computer has a local domain and information in this domain is accessed via NetInfo. In a NetInfo network, at least one network domain will be present and the computer that serves the network domain will have two NetInfo servers running. One server will be for the network domain and the other for the local domain. Computers that are part of the network domain will have access to the information stored in the network domain and any domains that may be above it.

Reading Information from the NetInfo database

NetInfo is an information storehouse. It is a passive database that stores information on configurations and resources. This means that NetInfo that information stored in the NetInfo database will have to be read out of the database to another application for it to be used.

There are two ways for information to read information from NetInfo. The first is through lookupd. Lookupd is a background process that is used to read information from NetInfo. Lookupd is used by applications that use the standard library (libc) to call lookupd. Applications can also read information directly from NetInfo using the NetInfo APIs (Application Program Interface). The application that controls logins (loginwindow.app) reads information directly from the NetInfo database.

Location of NetInfo

The NetInfo databases are stored in the /etc/netinfo directory. All computers that use NetInfo will have a local.nidb directory inside the netinfo directory. If the computer is a NetInfo server, databases for the domain(s) that the computer is serving will also be here. These databases will have the same name as the domain they server.

Structure of a NetInfo database

A NetInfo database contains directories that are organized hierarchically, similar to the way a file system is organized. Each directory has properties and values. These properties and values are the basic units of the administrative data that NetInfo stores. A property is referenced by its property key. The property key is simply the name of that property. Each property can have any number of values depending on the property.

Figure 1: Directory Browser window.

In Figure 1 the first directory under Directory Browser is the root directory and it is called "/", just like the root directory of the file system. It is lacking the property key "/name" so NetInfo references it by directory ID number, which is 0. Each of the other directories in the picture has the property key "name", and the value of that key is the name of the directory. If a directory does not have the key "name" NetInfo references it by ID number. Other property keys in Figure 1 are gid, realname, shell, passwd, home, shadow passwd, and uid. Each of these keys has a value except for shadow passwd.

The Template NetInfo Database

As part of the installation of Mac OS X Server, template files have been included on the hard drive. The template files are default files, similar to default preferences. The /usr/template/client/etc directory contains a default NetInfo database. This can be used to set a computer back to its shipping NetInfo configuration. Before this is done, the original NetInfo database should be moved to a new location. This is to ensure that any corruption that may exist in the old NetInfo database is not transferred to the new database.

Once the default NetInfo database has been restored the computer must be rebooted for the changes to take effect. After the computer has been

restarted the computer will boot into the Setup Assistant.

Making Backups

The NetInfo database stores some of the most important information on the computer and backups should be made frequently. However, a NetInfo database is in use while the server is booted into multi-user mode. Backing up the server in this mode may result in a database that is in flux (being changed while it is being backed up). If this is the case the backup will not properly load when it is restored.

There are two ways around this problem. The easiest is to boot the computer into single-user mode and manually copy the database at the command line. Example:

```
#cp -R /etc/netinfo/local.nidb /etc/netinfo/local.backup
```

This command will copy the local NetInfo database to a file called local.backup in the same directory as the original database.

The second way to backup the database does not require the server be rebooted, but it is more time consuming. Make a backup of the NetInfo database by selecting Save Backup from the Domain menu of NetInfoManager. Wait 5 minutes, then make another backup (use a different name so the original backup is not overwritten). Use FileMerge.app (available only if the developer packages are installed) or the command line utility "sum", to compare the two backups. If the two backups are identically either one can be used as the backup. If they are different, repeat the process until no differences are found.

To restore a backup, go to the Domain menu and choose Restore From Backup in NetInfoManager. Locate the backup and click the restore button. The computer will need to be restarted for the restored database to be read.

Files Not Used By NetInfo

For users that are not experienced with NetInfo, but are experienced with other Unix-style operating systems here is a list of files in the /etc directory that are not used when NetInfo is running; group, hosts, hosts.eq, passwd, netgroup, networks, printcap, protocols, rpc, and services. These files are still used if the computer is booted into single-user mode, but once NetInfo has started it takes over the functionality of these files.

A/UX: EtherTalk Support and MacTCP Issues (9/94)

I have heard that A/UX ships with EtherTalk already built into the kernel. Is this true?

If yes, how do I change the driver to run on the Macintosh IIfx and 1.2 to run on a Phase 1 network to update later revs to the driver?

I also noticed that MacTCP is shipped locked, and the MacX folders says not to add MacTCP Admin to A/UX. I did this anyway, so I could unlock MacTCP to change the IP addressing. This resulted in the system hanging.

After restarting, I tried newconfig with commando to turn on NFS and the Berkeley file system and restarted. The EtherTalk NB Card (rev K) did not get configured. I replaced MacTCP with a different, unlocked version, ran newconfig without commando, and the card was configured with no problem. I was using a Macintosh IIfx.

Why is MacTCP shipping locked? How do I make changes to it if I cannot use MacTCP Admin?

This article has been archived and is no longer updated by Apple.
The AppleTalk for A/UX product, which could be ordered as a separate product for A/UX 1.1.1 and was rolled into the A/UX 2.0 and 3.0 release, is based on the new AppleTalk Phase 2 protocol specification but is in no way tied to any version of the Macintosh OS EtherTalk driver.

The Ethernet driver running under A/UX is completely different from the driver written to support the Macintosh OS. The driver for A/UX is called ae6; you add and remove this driver from A/UX via the newconfig(1M) command. This driver does not have the same problems that the Macintosh OS driver has with the Macintosh IIci and Macintosh IIfx and, therefore, does not require the same revisions that the Macintosh OS driver needed.

There is no Ethernet support for the AppleTalk Phase 1 protocol suite. If you're using A/UX on an Ethernet and you want to use AppleTalk services, you must be attached to a Phase 2 network.

MacTCP for A/UX is a completely different version from the one we use under the Macintosh OSs. The version running under A/UX does not, and cannot, use the MacTCP Admin CDEV for configuration purposes. MacTCP running under A/UX gets all its configuration information from the kernel, making the Admin utility unnecessary. Use the ifconfig(1M) command to configure the IP network parameters under A/UX, or edit the /etc/NETADDRS file to change them permanently.

This shouldn't be necessary for a first-time installation since A/UX asks you for all configuration information it needs after you run the newconfig(1M) command to add an IP (ae6/bnet/ae6) network device driver to the kernel.

Mac OS X Server 1.x: Verifying Apache Installation

If the Apache web server is not running even though it has been selected to be a web server in the Setup Assistant, there is a way to verify its successful installation.
This article has been archived and is no longer updated by Apple.
Open the network settings from the Apple menu. Under the Services tab, make sure that the server has a name. Make sure the setting to be a web server is checked. If this is the case, the /etc/hostconfig file should include the following line:

```
WEBSERVER=-YES-
```

Check the console for any relevant errors by choosing the Console command from the Tools menu in the Workspace Manager.

Attempt to start the server from the command line by typing the following command at the prompt (open the Terminal application first):

```
apachectl start
```

If there is an error about the server's name, set the server name manually by editing the apache.conf file (/Local/Library/WebServer/Configurations/apache.conf). The setting you will edit is "ServerName". You must replace "localhost" with an explicit hostname (for example, "joesbox.apple.com") Be sure to use the hostname provided by your network administrator or ISP. Also, uncomment the line by removing the pound sign (#) before the "ServerName" on that line.

Please back up the config file before making any change by typing the following command at the prompt:

```
cp apache.conf apache.conf.old
```

After saving the changes to the config file, try restarting the server manually again from the command line.

Mac OS X Server: Configuring A Multiport Server With AppleTalk

With a multiport server, the Setup Assistant seems to hang when attempting to configure more than one port for AppleTalk.
This article has been archived and is no longer updated by Apple.
Setup Assistant is looking for a seed router on each port configured for AppleTalk. The server (a single host) cannot be present twice on the same network (configuring multiple ports for AppleTalk on the same network). So, it is polling for a seed router that would confirm that the server is on a routed network. The server can have multiple ports using Appletalk if each is in a different zone.

If the Setup Assistant does not find a seed router, it prompts you to set one up. If you are running the Setup Assistant before connecting your Ethernet cables, you should connect them at this point to get a correct configuration.

Mac OS X Server 1.x: Supported Browsers For Remote Administration Of Apple File Services

This article tells which web browsers can be used to administer Apple File Services remotely in Mac OS X Server versions 1.0 to 1.2.
This article has been archived and is no longer updated by Apple.
The following web browsers are supported:

- Netscape Navigator, version 4.0 or later
- Microsoft Internet Explorer, version 4.0.1 or later

Both require Java to be enabled.

Other browsers or versions may work but are not tested and therefore Apple does not provide support for such configurations.

Mac OS X Server 1.x: Exporting NFS Directories With NetworkManager

This article discusses NFS and how to export directories with NFS.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you do not already have an understanding of NetInfo domains, please read the following articles:

Article 60038: "**Mac OS X Server: What is NetInfo?**"
Article 30832 "**Mac OS X Server: Basic Introduction To NetInfo Domains**."

What Is NFS?

NFS stands for network filesystem. A filesystem in a Unix-style operating system generally means a directory or directory hierarchy. NFS is based on the client/server model. The server exports the filesystems, and the client imports them. With NFS it is possible to seamlessly share filesystems to other computers on a network. When users changes directories, they should not know that they are now looking at a remote filesystem. This is very powerful because it allows common resources to be stored on one computer, and accessed throughout the network. This would be an excellent idea for documentation like man pages, or read me files.

Selecting The Correct Domain

NetworkManager allows you to make modifications network wide, so you must select the domain you wish to change. If the computer is not part of a NetInfo network then the local domain is the only one available. If the computer is on a NetInfo network then the domain that you have access to must be selected.

The domain is selected at the top of the NetworkManager window in the field title "Domain." To reveal the larger domain hierarchy, click the disclosure triangle to the left of "Domain." The correct domain name can be typed or selected.

Once the correct domain appears in the "Domain" field, NetworkManager can be used.

A quick word on button conventions; buttons that have a star are for a new items, buttons that have a pencil is for editing items, buttons that have the international symbol for no are to delete items, and buttons that have a pencil and outline are to edit default profiles. Finally, buttons that have one face are for users, and buttons that have two faces are for groups.

Exporting Filesystems

To export a directory, click the "File Sharing" button on the left-hand side of the window. Clicking the "Shared Directories" tab shows the directories that are currently being exported (shared) to the network. This is also where new directories can be exported.

To share a new directory, click the share new directory button (a hard drive with a star). In the window that appears, use the "Select..." button along the right-hand side of the window to select the directory to be exported (shared). It is also possible to type in the path of the directory. All directories contained in the exported directory are visible to any client, but a client can only mount the exported directory, not nested directories.

Choosing a Destination

Next, the destination of the exported directory needs to be chosen. The destination is where the directory is exported to. There are three options, world, subnet, and clients.

Client is the most secure option because only clients with specified host names or that belong to specified netgroups are allowed to mount the directory. If the client option is chosen two buttons appear add and remove. Clicking the add button allows you to type in the name of the client or netgroup that the filesystem should be exported to. The name of the client or netgroup must be in the NetInfo database.

For more informaon on adding computers to NetInfo, please read:

Article 60026: "**Mac OS X Server: Using NetworkManager To Manage Computers In NetInfo.**"

The export to subnet option allows only a specified segment of the network to import these filesystems. For example, if 192.168.42.0 were entered into the subnet field then any computer on the 19.168.42.X subnet would be able to import the filesystem. **Note**: this is only true if the default subnet of 255.255.255.0 is still in place.

The last option is export to world and allows any client to import the directory. This means that if the server is on the internet it is possible for a client that is also on the internet to import the directories. However, this is also the easiest to configure.

The NFS Export Options

The nobody user is a default system user that has limited access privileges. For the highest level of security it is best to select treat all users as nobody. This is to be sure that remote users do not have access to secure information. There are times when other users should be selected, but they are not discussed here.

The other export options are listed in the following table:

Read Only	Does not allow changes to be made to the remote filesystem.
Export Entire Filesystem	Allows any directory below the exported directory to be imported directly.
Require Kerberos Authentication	Use a Kerberos server for authentication (a Kerberos server must be installed).

Note: Changes made with this program require the root password to the domain you are trying to configure. This may be only for the local domain (your computer) or it may be the root domain (the entire network). You should not try to change settings you do not have access to.

Mac OS X Server: NetInfo Delay During Startup

After installing and configuring Mac OS X Server, the computer may experience a significant delay at the Starting NetInfo section of the boot process.
This article has been archived and is no longer updated by Apple.
If your Mac OS X Server was set up to look for a NetInfo network or NetInfo server on startup, a delay of up to two minutes could occur if no NetInfo resources are available. After a timeout period, you can continue starting up by pressing the c key. For faster startup times you should turn off the option to use a NetInfo network server. You do this by opening the Preferences.app and selecting Network. Once the Network window has opened, click the NetInfo tab. In this pane there is only one checkbox. Uncheck this box, and the computer no longer tries to find a NetInfo network server at startup.

This delay could also be caused be improperly shutting down the computer. When this happens the information in the NetInfo database must be verified during startup. If a large NetInfo database is present the consistency check may take up to 20 minutes. Once the consistancy check is complete, the computer starts up properly.

For more information on NetInfo and what it does please see the following articles:

Article 60038 "**Mac OS X Server: What is NetInfo?**"
Article 30832 "**Mac OS X Server: Basic Introduction To NetInfo Domains**."

For information on creating a NetInfo network see:

Article 24719 "**Mac OS X Server: Creating a NetInfo Network**."
Published Date: Feb 18, 2012

Mac OS X Server: Processes

A process is a name for any running program that has its own memory space. Processes in Mac OS 8 include system software, application programs and background applications (such as FBC Indexing Scheduler, Control Strip, and Application Switcher). A background server process in Mac OS X Server is called a "daemon."
This article has been archived and is no longer updated by Apple.
In Mac OS X Server, several processes may be required to provide any given service. Starting an application also starts any other processes the application may need. If you know which processes are required for a certain service, you can check to make sure that they are running. A process that starts--or "spawns"--another process is called the parent process. A process that is started by a parent is called a "child" process. When a process is terminated intentionally, that is called "killing" the process. When a process stops working, it has "died." One step in troubleshooting a Mac OS X Server application is to determine if all its required processes are running. If a process is running but not responding, you may need to kill it.

Every process has a process identification number (PID) that is assigned according to order it was run. The first process that runs has a PID of 1. The second has a PID of 2 and so on. If a process dies or is killed, that PID is not reused. If the computer is restarted, the process count begins at 1 again.

You can use the ProcessViewer application to view and kill processes. This is similar to "force-quitting" an application in Mac OS 8. To do this, highlight a process in the process listing and choose "Quit Process" from the Process menu. If clicking the "Quit" button doesn't work, try the "Force Quit" button.

You open the ProcessViewer by choosing "Show All Processes" from the applications menu. It shows you the following information about each process:

- Name - The name of the process (not the full path)
- User - The name of the user that launched the process. System processes may show "root', "daemon", "www" or any user on your system.
- Status - Can be running, stopped, waiting
- % CPU - Shows what share of processor time a process is using. This is useful for performance analysis.
- % Memory - Shows what share of RAM a process is taking. This is useful for monitoring RAM consumption.

More Info

- Process ID- Shows the process ID, parent process ID, process group ID, Saved User ID and which terminal window the process was launched from (if applicable).
- Statistics - Shows total CPU time, virtual memory size and resident memory size.
- Path & Arguments - Shows which copy of a program was launched and the options (arguments) with which it was started.

Mac OS X Server 1.x: Directory Structure and File Types

This article describes Mac OS X Server's directory structure and file types.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The top (or "root") level of your hard drive is called "/" ("slash" or "root"). The Mac OS equivalent is Macintosh HD. Folders are called "directories." Directories located at the root level are referred to as /<directory name>.

There are three default directories (folders) at the root level of the hard drive. /Local, /System, and /Network.

/Local is for files specific to the computer that you're on.

/Local/Applications/Internet/ - Contains OmniWeb.app, the web browser. Required for reading some help files.
/Local/Library/Receipts - Contains .pkg files - Essentially installer logs for what's installed on your computer.
/Local/Library/WebServer - Default location for your web files. Can be changed in the Setup Assistant.
/Local/Library/MacOS/Users/ - Location for each user's startup disk and PRAM setting.
/Local/Users - Home directories for each user.

/System is for files specific to the operation of the computer

/System/Administration - The applications needed for administering the computer.
/System/Applications - These are programs and utilities that come with the computer.
/System/Documentation - Contains Read Me files, System Help.

/Network is for remote resources (devices, volumes, and users).

In general, applications folders contain applications.

/System/Applications contains applications that come with the computer /Local/Applications is a good place for administrators to install third-party applications that they want to make available to all users.

/Network/Applications is a good place for the Administrator to install applications for other NetInfo users to use on a NetInfo Network. (Used by the system, stored on the local drive or store a server). **Note**: If you move an application from its default directory, it may no longer work correctly.

Documentation folders contain help system files (.help) and other instructional documentation.

Users folders contain the users' "home" folders, where users keep their files.
The "home" folder for a user is also represented as "~username". If a user name is omitted, it is taken to mean the current user.

Filenames

Filenames are case-sensitive. myfile and Myfile, are different files.

The part of a filename after the last period is called the "extension." Extensions can be of any length and usually indicate a file's type. Some common extensions are .app (application), .rtf (rich text format), and .mbox (mailbox). If a file has multiple extensions, separated by periods, the last extension is the one the system uses to determine the file's type. Renaming a file to change its extension does not change its file type.

Also note that XXX.app is really an application wrapper. This is essentially a folder that contains what we think of as resources (other languages, picture and text files). To view its contents, open the Contents inspector and click on the "Open Application Wrapper..." button or use the keyboard shortcut (Command-Shift-O)

Pathnames

If you are typing a file path, you can save time by using some shortcut notation for the relative path.

./ refers to the current directory.

./Stuff/thing.html would be a file called thing.html in a directory called "Stuff", located in the current directory.

../ refers to the parent directory. You can have a ../ for each directory away from the root directory that your current directory is.

This information may come in handy when trying to decipher file locations or when entering commands in Terminal.app or in the Workspace

Manager "Go To" command under the Tools menu.

Expert Mode/Invisible files

Since Mac OS X Server is based on a Mach/BSD core, there are traditional Mach/BSD directories. However, these directories are hidden by default, in every account but the Administrator account. To view these files, you can choose "Expert" from the Preferences.app in /System/Applications (or under User Preferences in the Apple Menu). Expert mode can be triggered by changing to a directory that is only visible in Expert mode. To toggle back, update the viewer (command - U).

Note: Most tasks can be performed without having to use Expert Mode.

These additional items appear in Expert mode:

/bin - binaries, usually user-invoked commands
/cores - (core dump saved here after bad crash)
/dev - device driver interfaces. This is a link to /private/dev
/etc - directory where most configuration info is stored. This is a link to /private/etc
/lib - shared libraries
mach - a link (alias) to mach_kernel
mach_kernel - the kernel, the single most important file. This is the boot file listed in Open Firmware
/Net - a link to /Network/Servers
/private - contains /etc, /dev, /tmp, /var and more
/sbin - system-related binaries
/tmp - erased at restart. This is a link to /private/tmp
/usr - items related to applications and devices
/var - variables, spool and growable files and logs. This is a link to /private/var
.hidden - contains a list of files to be invisible in non-expert mode
.vol -

Files beginning with a dot are invisible.

Mac OS X Server 1.x: Printing With Print Manager

Before you can print to a printer, you must create a local or network printer resource.
This article has been archived and is no longer updated by Apple.
Before you can print to a printer, you must create a local or network resource. The Administrator password is required to create new printers.

AppleTalk and TCP/IP printing are supported over Ethernet. LocalTalk printing and serial printing to Apple printers is not supported either from Mac OS X Server or from MacOS.app.

Setting up a new printer connection

To set up a printer for use across a network, you create a "local" printer (on your computer) and then "export" it (make it available on the network) using the PrintManager application.

To create a new local printer, do the following:

1. Open the Print Manager application from the Apple menu.
2. Cick the Create... button in the printers window.
3. Make sure the appropriate communications driver is selected (AppleTalk, TCP/IP). Parallel is not supported.
4. Type in information. For AppleTalk printers, you can also click the Set... button and choose the printer and AppleTalk zone. For TCP/IP printing, choose LPR. You'll also need to enter the remote host (the name of the print server the printer is connected to) and the name of the queue. If there is no remote host, enter the printer's remote name.
5. Give the printer a local name.
6. Choose the PostScript printer description (PPD) file for your brand and model of printer.

To export a printer:

1. Open the Apple menu and choose PrintManager.
2. Click the Local tab.
3. Select the name of the printer you want to export and click Edit.
4. Enter the remote name for the printer.
5. Under Export, click Add.
6. Select the domain to export to and click Save.
7. Open the Apple menu, choose Computer Settings, then choose Network.
8. Click the Services tab, then click "Enable remote printing."

Print Services

Can I set up an AppleTalk-type (PAP) print server/spooler?

Apple does not include such a capability in Mac OS X Server 1.x. Third-party applications that provide spooler services are available.

For more help with printing, choose "Help" from the Help menu in the Workspace Manager and click on the "Printing" topic.

Mac OS X Server 1.x: Restarting/Shutting Down

Mac OS X Server versions 1.0 to 1.2v3 depend more on an orderly shutdown of the operating system than Mac OS 8 does. If the computer is turned off or restarted abruptly, there will probably be damage to the file system. If this happens, it is necessary to run the fsck command to check for and repair any file system damage.

Because Mac OS X Server is a server operating system, it should stay running all of the time.
This article has been archived and is no longer updated by Apple.

1. Normal Shutdown - Choose Quit from the File menu in the Workspace Manager. The following dialog box appears: "Do you really want to log out." You are given a chance to save any changes to unsaved documents.
2. Normal Power off - Press the Power key on the keyboard. The following dialog box appears: "Do you really want to turn off the computer." Clicking the "Turn It Off" button shuts down the computer properly. You should be given a chance to save and changes to unsaved documents.
3. Command Line - If you are logged on as Administrator, or as a user that is a member of group wheel, open Terminal.app from /System/Administration or from the Apple menu. If you are not logged in as the Administrator, type su root. When prompted, type the Administrator password. Type halt or reboot. The computer should shut down or restart properly.
4. Mini Monitor - Type Control-Power. You should get a small dialog box that says "Restart or Shutdown" Type R to restart, or type H to shutdown. Type C to continue. **Warning**. You may lose unsaved data. Nonetheless, Mac OS X Server should still properly shut itself down.
5. Command-Control Power - Likely to cause file system damage. May be the last resort in some circumstances. You **must** start the computer up in single-user mode and run fsck.

Mac OS X Server 1.x: MacOS.app Disk Access Modes

This article discusses the tradeoffs among the three access modes available to MacOS.app: Shared, Exclusive, and SCSI.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you are just running Mac OS productivity applications, you should not need to switch the access mode for any of your disks or partitions. However, in case you need to run disk utilities such as Disk First Aid, Disk Copy, or Drive Setup, you may need to (temporarily) switch the access mode of one or more of your disks or partitions. The "Blue Volume Mount Options" control panel is provided to allow you to set these access modes for individual disks and disk partitions. It is described below, after the explanations of the three access modes.

You can determine in which mode a volume is being accessed by selecting it in the Finder and choosing Get Info from the File menu. The dialog that appears includes a "Where" string that describes the mode in which the underlying disk is currently being accessed, along with an indication of the physical disk to which it corresponds. Disks accessed in Shared mode have "Shared" in this string. Similarly, disks accessed in Exclusive mode have "Exclusive" in this string. Disk image files (which are always accessed in Exclusive mode) list the pathname of the disk image file. Disks accessed in SCSI mode have a string identical to the one they would display if running native Mac OS; typically this string gives the SCSI Bus number and SCSI device ID of the disk.

For disks accessed in Shared or Exclusive mode, the SCSI bus and ID (or ATA/IDE ID) are not given; instead, they are identified in the "Where" string by their Mac OS X Server device name. In order to understand how Mac OS X Server names disk devices, you must consult the documentation for Mac OS X Server. Briefly, SCSI (and ATAPI) disks have names like "sd0", "sd1", etc. ATA/IDE drives have names like "hd0"; and floppy disks have names like "fd0". Disk devices may also have more than one HFS(+) partition; the first HFS(+) partition of "sd0" is "sd0_hfs_a", the second is "sd0_hfs_b", etc. Disks without partition maps (such as floppies and ISO9660 CD-ROMs) are treated as though they consisted of a single HFS(+) partition, comprising the whole disk (e.g., "sd0_hfs_a").

Shared Mode

MacOS.app supports mounting HFS(+) volume(s) which are already mounted by Mac OS X Server. This mode of access is called Shared mode because all the files and folders on Shared volumes are simultaneously accessible from Mac OS applications running inside MacOS.app and Mac OS X Server applications running outside of it. Shared mode was chosen as the default file system access mode because it does not require the user to unmount a volume from one environment before mounting it in the other.

Although Shared mode access provides the highest level of interoperability between Mac OS and Mac OS X Server applications, it is not compatible with Mac OS applications that require low-level disk access. Mac OS productivity applications are not affected by this incompatibility since they access files and folders through the high-level interface provided by the File Manager. On the other hand, disk utility programs typically require low-level disk access. Examples of disk utilities that require Exclusive mode access are Disk First Aid, and Norton Disk Doctor. Examples of disk utilities that require SCSI mode access include Drive Setup, and FWB's Hard Disk Toolkit. None of these utilities function correctly on a volume accessed in Shared mode.

Exclusive Mode

MacOS.app supports mounting HFS(+) disk volumes in a mode that permits block-level access. This mode permits certain disk utilities (such as Disk First Aid and some operations in Disk Copy) to run that would not work with a disk accessed through Shared mode. This is called Exclusive mode because disks accessed by MacOS.app in this mode appear exclusively in MacOS.app and cannot be accessed by Mac OS X Server applications. You can request that a disk or partition be accessed through Exclusive mode by using the "Blue Volume Mount Options" control panel.

When Mac OS X Server first detects an HFS(+) disk partition (either when starting up or when a removable disk is inserted into a drive) it mounts it and notifies MacOS.app. MacOS.app is also notified about disks that are not recognized or mounted by Mac OS X Server. When MacOS.app notices a disk that has been mounted in Mac OS X Server for which the user has selected Exclusive mode, it asks Mac OS X Server to unmount the disk and then mounts it exclusively.

Because it remains under the control of the Mac OS X Server SCSI drivers, a disk accessed through Exclusive mode cannot be accessed through the Mac OS SCSI Manager, even if the underlying disk is a SCSI disk.

Volumes accessed in Exclusive mode can be read from and written to, regardless of the access rights of the user.

Disk image files like the supplied StartupDisk.img are always accessed through Exclusive mode.

The choice between Exclusive and Shared mode access can be made on a per-partition basis for disks with multiple HFS(+) partitions.

Removable disks accessed througgh Exclusive mode are usually ejected upon Shutdown or Restart of MacOS.app. CD-ROMs are an exception and are not ejected upon shutdown, in order to more closely mimic the behavior of Mac OS.

SCSI Mode

MacOS.app supports SCSI disk devices that are recognized by Mac OS X Server. MacOS.app provides a special compatibility mode for accessing these devices through the SCSI Manager, just as they would be accessed under the native Mac OS. This mode provides the highest level of compatibility with Mac OS disk utilities, especially with those that require SCSI access, like Drive Setup.

Like Exclusive mode, SCSI mode must be selected by using the "Blue Volume Mount Options" control panel. When MacOS.app first detects a disk for which SCSI mode has been selected, it attempts to unmount it from Mac OS X Server. If this succeeds, MacOS.app can access it in SCSI mode without fear of interference from Mac OS X Server applications.

Volumes accessed in SCSI mode can be read from and written to, regardless of the access rights of the user.

Unlike the choice between Shared and Exclusive mode access - which can be made on a per-partition basis for disks with multiple HFS(+) partitions - accessing a disk through SCSI mode precludes any other sort of access, either by Mac OS X Server or through Shared or Exclusive mode in MacOS.app. One consequence of this is that a disk containing a UFS file system partition that is mounted by Mac OS X Server cannot be accessed through SCSI mode in MacOS.app. For example, if your system has only one hard disk and has separate partitions for UFS and HFS(+) file systems, you cannot access the disk in SCSI mode.

Removable SCSI drives without media present become reserved for SCSI mode access if probed with a SCSI disk utility like Drive Setup.

SCSI mode access is not available for ATAPI devices (which includes the internal CD-ROM and optional Zip drive on some Power Macintosh G3 models) or IDE/ATA devices (which include the internal disks on most non-Server Power Macintosh G3 models).

Switching Modes: The "Blue Volume Mount Options" Control Panel

In the "Apple Extras" folder of the supplied StartupDisk.img is the control panel to set the desired access mode for disks and disk partitions. Disks can be accessed in one of three modes (Shared, Exclusive, or SCSI), although not all disks permit access in SCSI mode. A disk cannot be accessed in SCSI mode if it is not a SCSI disk (e.g., floppies, ATA/IDE/ATAPI disks). Nor can it be accessed in SCSI mode if there is a UFS file system mount point active on the disk at the time the mode switch is attempted (either when the control panel is launched or when MacOS.app is starting up).

Launching the "Blue Volume Mount Options" control panel displays a single dialog which can be dismissed by quitting the control panel or closing the window. Any changes that are made are stored immediately upon quitting the control panel, although most changes do not take effect until MacOS.app is restarted.

Figure 1, Volume Mount Options control panel

The control panel lists all the disk drives and disk partitions that it finds on the system, together with three columns of radio buttons, named after the three possible modes of operation: SCSI, Exclusive, and Shared. If a radio button does not appear in one of the columns, it means that the corresponding mode is not available for that drive (for example, SCSI mode for an ATAPI CD-ROM drive). If a disk partition is already mounted in Shared or Exclusive mode, it appears in the control panel under that name (for example, "sd0_hfs_a"). If it is a removable drive with no disk present, it appears under the name of the drive (for example, "sd0"). Finally, if it is being accessed through SCSI mode, it appears labeled with its SCSI Bus and device ID (for example, "Bus 0, ID 0"). In each case, these labels should correspond closely to what you find in the "Where" string displayed in the Finder's "Get Info" dialog for that volume.

The same disk may appear under different names at different times in the "Blue Volume Mount Options" control panel depending on whether there is a disk in the drive. For example, the internal ATAPI CD-ROM drive on a Power Macintosh G3 appears as "ATA drive sd0" when there is no CD-ROM in the drive, but as "HFS partition sd0_hfs_a" when a CD-ROM is in the drive.

If a disk has multiple HFS(+) partitions, they can be accessed in Shared or Exclusive mode independently from one another. In other words, the choice between Shared and Exclusive mode can be made on a per-partition basis. Similarly, Mac OS X Server can mount a UFS partition from a disk containing one or more HFS(+) partitions, each of which may be accessed in Shared or Exclusive mode. SCSI mode is different, though, because it requires complete control of all requests going to the disk. Therefore, selecting SCSI mode for one partition on a disk causes all the partitions on the disk to be accessed through SCSI mode. If you try this, the settings of the radio buttons automatically reflect this constraint. Similarly, you cannot select SCSI mode for a disk containing a mounted UFS file system. If you do select SCSI disk mode for a disk that contains an unmounted UFS file system, your selection is honored. You cannot mount that UFS file system in Mac OS X Server while MacOS.app is accessing the disk in SCSI mode.

For fixed, non-removable disks, changes made through the "Blue Volume Mount Options" control panel do not take effect until MacOS.app is restarted. Removable disks can be ejected and reinserted without restarting MacOS.app.

TA44160_Mac_OS_X_Server_x_MacOSapp_Disk_Access_Modes.pdf

The disk mode selections made through the "Blue Volume Mount Options" control panel are only requests. In some cases, it might not be possible to honor them and MacOS.app may mount a disk in a mode other than the one selected in the control panel. To find out what mode a volume is being accessed in, consult the "Where" line in the "Get Info" window of that drive.

Mac OS X Server 1.x: Apple File Services Features

Apple File Services is an Apple File Protocol 2.2 (AFP)-compliant server. Apple File Services fully supports version 2.2 of the AFP specification (the same as AppleShare IP 5.x and later).
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Apple File Servers has the following features:

- Optimized for use with AppleShare 3.8.2 client.
- Supports AFP over TCP/IP and AppleTalk.
- Provides high performance and scalability.
- Supports Mac OS Extended Format (HFS+) volumes
- Supports volumes sizes up to 2 terabytes
- Enforces AFP access privileges.

The following table shows the maximum allowed values for properties of the server:

Maximum number of...	Specification
Connected users over TCP/IP or AppleTalk	1 100
Unique open files	3 000 to 4 000*
Physical volumes	50
Share points	500
Users and groups	10 000
Group memberships per user	42

* Depends on the number of connected users.

Miscellaneous properties:

- TCP port for Apple Filing Protocol (AFP): 548
- TCP port for Remote Administration: 311

Serial Cables: Extreme Length Can Generate Noise (11/94)

I've connected a Macintosh SE to my MV15000 (Data General host) through the serial port using a cable wired according to the pinouts documented in the Tech Info Library.

When a terminal line is enabled, the host sends a "welcome" message to the terminal. If the Macintosh is not already in the terminal emulation program, the host receives arbitrary noise back on the line, causing the operating system to disable that port.

Can you shed any light on why this may be occurring, and where I could look for a solution?

This article has been archived and is no longer updated by Apple.
When a Macintosh system is turned on and the System software is loaded, the transmit lines of the serial ports are in a high-impedance mode. This does not change until a terminal program, such as MacTerminal, is run.

Arbitrary noise back on the Macintosh transmit line could result if the cable is too long. The maximum serial cable length that the Macintosh supports is 50 feet. If the cable is longer than this, you may want to use short- haul modems.

You did not provide us with the pinouts that you're using. We are providing the following as a reference:

RS-422 and RS-232 Equivalents

Pin RS-422 name RS-232 equivalent
1 HSKo (handshake out) DTR (data terminal ready)
2 HSKi (handshake in) CTS (clear to send)
3 TXD- (transmit data negative) TXD (transmit data)
4 GND (signal ground) GND (signal ground)
5 RXD- (receive data negative) RXD (receive data)
6 TXD+ (transmit data positive) leave unconnected
7 not connected not connected
8 RXD+ (receive data positive) must be grounded to pin 4 (on Macintosh RS-422 connector)

Mac OS X Server 1.x: Apple File Services Installed Files

Apple File Services installer is integrated into the core OS installer and installs the items below into appropriate locations within the local file system hierarchy.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Apple File Services Server
(/usr/sbin/AppleFileServer)
The core AFP server application, which is a daemon process.

Server Control API Framework
(System/Library/PrivateFrameworks/ServerControl)
The Server Control API framework is shared with QuickTime Streaming server

Remote Admin CGI
(/System/Library/RemoteAdminServer/CGI-Executables/)
A lightweight pass-through process that is invoked by the web server and in turn transmits requests to the Web-Based Admin Server. It also receives the reply from the Web-based Admin Server and transmits it back to the web server, which then sends the reply back to the browser.

Remote Admin Server (/System/Library/RemoteAdminServer/FastCGI/RemoteAdminServer)
Handles authentication and majority of admin tasks.

Remote Admin Java and Image Files (/System/Library/RemoteAdminServer//Documents/)
Java classes are used for authentication and password encryption.

Log Files: There are two log files kept by the server:

- The AFP server creates a log file at /Local/Library/AppleFileServices/AppleFileAccess.log and logs key events if the "Enable Log" preference is set in Remote Administration.
- The server error log file is located at /Local/Library/AppleFileServices/AppleFileError.log. This log is always enabled.

Mac OS X Server 1.x: Apple File Services Configuration and Setup

This article describes the configuration and setup of Apple Files Services under Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Apple File Services depends upon the Mac OS X Setup Assistant to configure basic setup information, including:

- AppleTalk Name
- Whether Apple File Services is enabled
- Whether Apache Web server is enabled
- Whether AppleTalk and TCP/IP is enabled

After initial setup, these settings, as well a users, groups, and sharing for Apple File Services, are configured using Remote Administration. For help setting up and using Remote Administration, please see:

Article 60063: "**Mac OS X Server: Using Apple File Services Remote Administration**"

Both Apple File Services and Apache must be enabled.

Even if you only select Apple File Services, the Apache Web server will be launched on startup since it is required for Remote Administration.

If Apple File Services is enabled with the Setup Assistant, an entry is made in the file /private/etc/hostconfig. This causes RemoteAdmin to launch. When Remote Admin launches, it looks for the "autostart" flag in the NetInfo database. If this flag is either missing or set to true, Remote Admin opens AppleFileServer. The only condition that would cause the File Server not to start up is if this flag is set to false. This requires changing the setting in Remote Administration.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Apple File Services Required Processes

This article outlines the required processes for operating Apple File Services under Mac OS X Server.

For more information on processes under Mac OS X Server, please see article:

Article 60053: "**Mac OS X Server: Processes**."
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

AppleFileServer runs over either TCP or AppleTalk and requires that TCP and/or AppleTalk be configured on the system.

The processes that show AppleFileServer is active are AppleFileServer and AdminWebServer.

AppleFileServer runs from a PIPE out of the AdminWebServer server (an HTTP server) and once running shows up in a process:

```
ps ax |grep AppleF
 632 ?  I     0:00 AppleFileServer /tmp/afpserver_PIPE
 639 ?  S     0:00 AppleFileServer /tmp/afpserver_PIPE
```

AdminWebServer appears in the process list as well:

```
ps ax |grep Admin
 557 ?  S     0:00 /usr/libexec/AdminWebServer -f
/System/Library/RemoteAdminServer/Configuration/apache.conf
 559 ?  I     0:00 /usr/libexec/AdminWebServer -f
/System/Library/RemoteAdminServer/Configuration/apache.conf
 560 ?  I     0:00 /usr/libexec/AdminWebServer -f
/System/Library/RemoteAdminServer/Configuration/apache.conf
 566 ?  I     0:00 /System/Library/RemoteAdminServer/FastCGI/RemoteAdminServer
```

Notice that the final process listed is the FastCGI which executes the remote administration of the AppleFileServer.

Remember that in the process viewer, the AdminWebServer processes show up as 'apache' EXACTLY like the HTTP server that is serving files on port 80.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Using Apple File Services Remote Administration

This article describes how to use Apple File Services Remote Administration.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Using Remote Administration requires the following:

- Set up the following in the Mac OS X Server Setup Assistant:
  - TCP/IP services must be enabled on Mac OS X Server.
  - The Apache Web server must be enabled on Mac OS X Server.
  - Apple File Services must be enabled on Mac OS X Server.
- You must have a client computer with a TCP/IP connection to the server. This connection can be over a LAN, WAN, or a dial-up connection. If you are accessing it through a firewall, make sure that port 311 is not filtered.
- Netscape 4.0 and Internet Explorer 4.0.1 or higher. Note, that the current version of OmniWeb does not work with Remote Administration.

Users of Remote Administration in AppleShare IP 6.1 should be immediately familiar with Apple File Services Remote Administration. To Access the Remote Administration program, enter in the following URL:

```
http://www.yourserver.com:311
```

where "www.yourserver.com" is the hostname of the server,

- or -

```
http://nnn.nnn.nnn.nnn:311
```

where nnn.nnn.nnn.nnn represents the IP address of the server.

You are prompted to enter the Administrator name and password:

Figure 1, Remote Server Administration login

For the initial login, use the root password. The root user may log in with the name "root", "Administrator", or "administrator." Remote Administration uses a Java Applet to encrypt all transactions containing a password, so administrators need not worry about sending the root password over the network. After the initial login, the administrator can create other users who are administrators of Apple File Services, but do not hold any special privilege within Mac OS X Server.

Note: Unlike versions of AppleShare for Mac OS 8, the user name is case sensitive. This applies to both logins in the Remote Administration, and through the Chooser.

Once you have logged on, the status screen appears:

Figure 2, Remote Server Administration status screen

The toolbar at the top of the page appears on every page within Remote Administration. It is in many respects identical to AppleShare IP 6.1 Remote Admin. However, you cannot administer the Web server, mail server, or print server applications in Mac OS X Server, with this version of Remote Administration.

Administering Users & Groups

Adding, editing, and deleting Users and Groups within Remote Admin is mostly self-explanatory. The following options, available in AppleShare 6, are not available for Apple File Services:

- Program Linking
- Disable Log on as of _____
- User may change Password (This is always enabled)
- Require new password on next log on

When you create users within Remote Administration, these users are kept in the NetInfo database. The user's AppleShare name is entered into NetInfo as the "realname." The Internet alias is entered into NetInfo as "name." If you fail to give a user an Internet alias, Remote Admin will give the user a default name of "uXXX", where XXX is the Unix-style User ID. For example, User ID (uid) 810 would have a name of "u810". Following is a user's account from the NetInfo database (as shown in NetInfo Manager). This user has the realname "Teacher", no name, and is an Administrator of Apple File Services. In the Network Manager application (which uses the same database), the NetInfo name property is called "Internet Alias" and the NetInfo realname property is called "Full Name".

Figure 3, NetInfo Manager user's account example

While NetInfo is where all the Unix-style users are kept, users created with Remote Administration do not have access to the Mac OS X Server console; they are only allowed to log on to the Apple File Services server.

Conversely, when you create users within Mac OS X Server using Network Manager, that user has access to AFP services, in addition to other logon privileges the user may have (to the console, FTP, and so forth).

When you create an administrative user from Remote Administration, that user is only an Administrator over Apple File Services. That means that the user can log into Remote Administration, and that when the user logs in througgh the Chooser, she sees mounted HFS and HFS+ volumes, rather than share points. However, this administrative user has no special privileges in Mac OS X Server other Apple File Services.

Setting up Share Points

Apple File Services will allow you to create a share point on any Mac OS Extended format disk. You can make either the entire disk - or specific folders on the disk - share points. You can also make removable disks (such as CD-ROM discs) or folders on removable disks share points. Hard drives formatted as Standard HFS are not supported under Apple File Services.

When you set up share points in AppleShare IP, all of the share points and privileges information is kept in one location: the AppleShare PDS file. With Mac OS X Server, these two preferences are kept in distinct places:

- Sharepoint information is kept in the NetInfo database. This is only the information about which directories are shared.
- Privileges are kept in the filesystem itself.

With HFS+, Apple included the ability to define privileges within the file's header block in the filesystem. There is no separate file to track privileges as there were with Mac OS versions of AppleShare. These privileges are identical to Unix-style permissions and are accessible via command-line utilities such and `chown` and `chmod`.

Another difference from AppleShare IP is the Group field. In previous versions of AppleShare, there were three classes of users: Owner, User/Group, and Everyone. The User/Group could either be an individual user or a group of users. With Apple File Services, this field must be a group.

Because of the difference in the way privileges are stored in AppleShare for the Mac OS and Apple File Services, disks that were previously set up for sharing over AppleShare will not maintain privileges when shared with Apple File Services. Apple File Services will not recognize information located in the AppleShare PDS file, nor is there any way to convert that information into privileges understood by Apple File Services.

Since privilege information is kept in the filesystem itself, Apple File Services does not support privileges on read-only volumes, such as CD-ROMs. However, it is still possible to share this volume. The privileges look like this:

Figure 4, Apple File Services privileges

Privileges for read-only volumes will be read-only for everybody, and there is no way to change them.

Other Server Settings

These are the other server options available under Remote Administration:

Figure 5, Remote Administration Server Settings

These changes require a server restart to take effect. **Note:** Toggling guest access is immediately active over TCP/IP. Guest logon over AppleTalk only changes after a restart. TIP: Since these settings are also entered into NetInfo, NetInfo Manager is a good place to check for correct information, when troubleshooting AFP issues.

Figure 6, Checking information in NetInfo Manager

Backing up and Restoring Users & Group and Privileges.

A backup option includes the command line tools, part of BSD 4.4. The most common is the `tar` command. Tar does not retain user and group privileges like backing up an ASIP server. These only backup UFS volumes. To back up HFS volumes, use a third-party utility.

Mac OS X Server 1.x: Apple File Services Open File Limitation

This article discusses the maximum number of files that can be opened by Apple File Services.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Apple File Services can handle 3 000 to 4 000 unique files open on client computers. This limit is expressed as a range because of the way Apple File Services keeps track of open files. The server has a total of 4 000 file descriptors with which it can keep track of open files. Each user who is logged in over AFP also takes one of these 4 000 file descriptors. Furthermore, a Mac OS file may have either a data fork and a resource fork. While the user perceives this as one file, the server sees it as two files for the purpose of file descriptors. Therefore, if ten users were logged on through AFP and each user had 10 files open (each file with both a data and a resource fork) this would count as 210 file descriptors against the total limit of 4 000.

Note: The open file limit operates differently than in recent versions of AppleShare IP. Under AppleShare IP the server support 3 000 instances of 346 unique files. Apple File Services makes no such distinctions between unique and duplicated open files.

For more information on other Apple file sharing limitations, please see:

Article 15460: "**AppleShare File Sharing: Chart of All Limitations**."
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Apple File Services Compared To AppleShare IP

Apple File Services does not have all of the options available under versions of AppleShare IP for Mac OS 8.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Some functions of AppleShare IP that are not part of Apple File Services include:

- Duplicate user, import, export
- Batch-change user options
- Log on greetings
- Multi-homing support
- Dynamic server name change (You must restart Apple File Services to change the server's AppleTalk name)
- Setting access privileges on read-only volumes, such as CD-ROM
- Support for HFS or UFS volumes
- Application launch limit support
- DOS short names support
- ProDOS support
- Cannot enable or disable just AFP/TCP or AFP/AppleTalk
- Idle disconnect
- Automatic reassignment of access privileges after a user is deleted
- Web-based administration from OmniWeb browser on Mac OS X Server platform
- Clear text authentication only; no extensible UAM mechanism
- Ejectable media is not shared automatically. When it or its sub-directory is shared explicitly, the access privileges are set to read-only for everyone
- Password related convenience features:
    - Password expiration
    - Minimum password length
    - Disable account after a specific number of failed attempts
    - Change ability to allow user to save password for automatic log on
- There is no serial number for Apple FIle Services as there was for AppleShare IP

Cache

Previous versions of AppleShare for the Mac OS 8 used a RAM cache to increase performance. As files were copied from the server, AppleShare would store them in RAM so that the next time the files were copied, the server would be faster finding and transferring it from RAM instead of the disk. Apple File Services does not use this mechanism. Instead, it leverages on the speed of the underlying OS to provide fast file transfers. There is no cache setting to adjust, and the Apple File Services process on the server allocates RAM as it needs it.

Mac OS X Server 1.x: Troubleshooting Apple File Services Remote Administration

This article describes how to troubleshoot Apple File Services Remote Administration under Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you don't know the host name of the Web server:

On the server computer, open the Apple menu and choose Computer Settings, then choose Network. In the Network settings panel, click the Services tab. The server name should be listed here. You can also log into the server using its numeric IP address.

If Remote Administration does not recognize the user name and password you enter:

Be sure you have entered the user name and password for a user with administrator (root) privileges. If the user name and password continue to fail, you can log in by typing "Administrator" and the password for the Administrator user (root) of the server computer. Passwords are case sensitive.

If you're unable to connect to or log in to Remote Administration:

Make sure your computer is connected to the network properly. Try logging in to Remote Administration using the TCP/IP address for the server.

If you are able to log in using the TCP/IP address, then you may have entered the URL incorrectly. The URL should be similar to this:

http://server.domain.com:311

The "server.domain.com" is the host name of the Web server plus the domain of the organization.

If you are logging in to Remote Administration from the Internet, be sure the name is the Internet DNS name for your Web server and not the local domain name.

If you are logging in to Remote Administration from the Internet, be sure the DNS server is available, or use the IP address.

If you receive a "504" or proxy time-out error message, ask your proxy server administrator to allow write access for the Web server on port 311.

If this is not possible, turn off any proxies set up in your web browser and select the option to connect directly to the Internet. Then, try again.

You can also make sure Apple file services is turned on and connected to the network:

1. Make sure you can reach the other computer over the network (try pinging the other computer)
2. Log in to your server computer as Administrator.
3. Open the Apple menu and choose Server Administration, then choose Assistant.
4. In the panel, select Setup Assistant and follow the onscreen instructions to turn on Apple file services.
5. Restart the server computer.

If you have other network services running on the server computer, you may want to notify users first.

If you're sure Apple file services is turned on but you are unable to log in to Remote Administration:

Two different processes are required for Remote Administration to work: RemoteAdminServer and AdminWebServer. To find RemoteAdminServer, open the ProcessViewer (located in "Server Administration" under the Apple Menu). You should see RemoteAdminServer listed in the Process Listing.

The AdminWebServer shows up as "apache" in the ProcessViewer, but not all processes named "apache" function as the AdminWebServer. To make sure that the correct apache processes are running, follow these steps:

1. Click the triangle at the bottom of the ProcessViewer to view More Info.
2. Click the "Path & Arguments" tab in that section.
3. Type 'apache' (without quotes) in the Find box at the top of the window. This should display only those processes whose name contains "apache".
4. Three of the listed processes should have "/usr/libexec/AdminWebServer" in the "Full Path" section of the "Path and Arguments" tab.

Alternatively, you can type the following into the command line (Terminal.app):

```
ps aux | grep Web
```

This gives you a long display of all the processes running on the server whose name contains "Web". Look for /usr/libexec/AdminWebServer.

There should be three instances (copies) of this.

If you are unable to find either AdminWebServer or RemoteAdminServer, try restarting Apple File Services using the Setup Assistant

If they both appear in the list, you can use ProcessViewer to stop the processes, then restart Apple File Services using the Setup Assistant.

If users say the server is slow:

- Make sure it's not a network-wide issue. Log onto another server to test performance
- Have Admin check histogram in Remote Admin to see what user level is at versus connected user activity for possible culprits.

Mac OS X Server 1.x: Troubleshooting Apple File Services

This article describes how to troubleshoot Apple File Services under Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If the server doesn't appear in the Chooser:

- Make sure AppleTalk is active on the server computer.
- Make sure AppleTalk is active on the user's computer and that the correct network connection type is selected in the Connect via pop-up menu in the AppleTalk control panel.
- Make sure the user has the correct version of the AppleShare client software installed on their computer.

Log in to the server computer as Administrator (root), open the Apple menu and choose Server Administration, then choose ProcessViewer. Look for AppleFileServer in the Name column.

If AppleFileServer doesn't appear in the ProcessViewer, try restarting the server using the Setup Assistant:

- Make sure users are looking in the correct AppleTalk zone and that they are looking for the correct name.
- Make sure the user's computer and the server computer are connected to the network properly.

If a user is disconnected unexpectedly:

- Make sure another administrator didn't disconnect the user.
- Make sure the volume the user was connected to is mounted.
- Make sure the user's computer and the server computer are connected to the network properly.

If a user can't log in to the server:

- Make sure the user entered the correct name and password.
- Make sure you have created a share point and assigned access privileges for the user or a group to which the user belongs.
- Make sure the maximum number of connections has not been exceeded.
- See if the user can connect to the server via AppleTalk using the Chooser. Then check to see if the user can connect to a Web site througgh TCP/IP using a browser. If the user can connect through one protocol but not the other, there may be a problem with AppleTalk or TCP/IP settings.

If a user's password doesn't work:

- Give the user a new password, then have him or her try to log in again.

If a user forgets his or her password:

- Give the user a new password.

If an administrator forgets his or her password:
Another administrator can give te administrator a new password. If you have not created another administrator user, you can log in to Remote Administration by typing Administrator and entering the password for the Administrator (root) of the server computer.

If a user cannot find a file or folder:

- Be sure the user has Read or Read & Write privileges to the folder. Log in to the server on the user's computer and select the file or folder. Choose Sharing from the File menu to see the folder's access privileges. Change the folder's access privileges, if necessary.

If the access privileges a user sets keep changing:

- The user may be setting an invalid combination of access privileges. You can have the user select valid access privileges or install the AppleShare client software version 3.8.2.

If a user cannot access a CD-ROM disc:

- Make sure you've made the disc a share point.

If some users see a volume size that is different from the volume size displayed on the server:

- Users who have versions of system software earlier than System 7.5 cannot see large volumes. Update the client computers to Mac OS 8.5 and AppleShare 3.8.2.

If users say the server is slow:

- Make sure version 3.8.2 or later of the AppleShare client software is installed on users' computers.
- Make sure users connect to the server computer by using TCP/IP.

Mac OS X Server 1.x: Starting and Stopping Apple Files Services

This article describes how to start and stop the Apple File Services server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Starting The Server

To start the server:

- Log into the Remote Administration web page.
- Click Status, then click Start Server.

If the server fails to start up:

- Check the error log on the server computer.
  On your server computer, look for the file named AppleFileError log in this location:
  /Local/Library/AppleFileServices
- Be sure the server has a name and that the name is different from that of other server computers or any Macintosh computers with file sharing turned on.
- Make sure the server has at least one Mac OS Extended format volume available to share.
- Be sure your server computer is connected to the network properly.
- If you have a NetInfo master domain set up on your network, be sure your server computer is configured properly to connect to it. For information about setting up a NetInfo master domain, see Server Administration Help on your server computer.

Stopping The Server

Before you stop the server, you may want to notify users.

To stop the server:

1. Log into the Remote Administration web page.
2. Click Status, then click Stop Server.
3. In the Default Shutdown Message page, type the number of minutes before the server stops and, if you like, a message for users. If you type more than five minutes, users can continue to log in until the final five minutes.
4. Click Shutdown.

Users who are logged in to the server and who can receive messages see a standard warning message, which includes any message you entered.

If the server fails to stop:

On the server computer, open the Apple menu and choose Server Administration, then choose ProcessViewer. Select AppleFileServer in the Name column and click Stop Process.

Cancelling Stopping The Server

To cancel stopping the server:

- Click Cancel Shutdown in the Status page.

The server sends a message notifying users that you have cancelled shutting down the server.

Macintosh: Third-Party Drivers for High-Speed Printers

I have HP RuggedWriter 480 printers and Printronics P300 High-speed line printers. I want to use the Macintosh with a 4D database to print labels in mass volumes at high speed using the printer-resident font characters.

Currently, I have drivers from GDT (of Canada) that let me print to these printers from the Macintosh, but at very low speed.

1) Do you know of any drivers that work on these high-speed printers using the printer-resident font characters?

2) Do you know of any other printer and drivers that will do the job?

This article has been archived and is no longer updated by Apple.
We know of three possible sources: GDT Softworks, Orange Micro, and Insight. Most support fonts built into printers, but none lists your specific printers in their product literature. Perhaps you should contact the printer manufacturers to discuss their specific requirements.

For more information, search the Tech Info Library under: "GDT Softworks", "Orange Micro", and "Insight".

Mac OS X Server 1.x: Maximum Virtual Memory

This article details the maximum Virtual Memory Mac OS X Server uses and whether it can be configured.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The system is free to try and allocate it's full 4 GB of address space. There is no limit imposed by the system other than running out of space on the file system where the swap file exists.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: The ".dir5_0.wmd" File Explained

Under Mac OS X Server, you may notice a file named ".dir5_0.wmd". This article tells what the file is and what it does.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

This file is the equivalent of the Desktop Database under Mac OS 8, and stores things like icon placements and sort order. You can delete it without concern. Note that other '.' files, which are invisible unless you are in Expert mode, are often needed by various Unix-compatible programs, and should not be deleted.

Mac OS X Server 1.x: Support Information For Apache Web Server

This article tells where to get more information about Apache server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The Apache documentation is preinstalled with Mac OS X Server in the /System/Administration/Services/apache directory. There is a link to this directory in the /Local/Library/WebServer/Documents/ directory.

The latest information on Apache is posted on Apache's Web site at: http://www.apache.org/.

Beyond the support of basic installation, configuration, troubleshooting and recovery offered by Apple, many public information sources provide broad support for Apache. A few popular sites include:
Apache FAQ at http://www.apache.org/docs/misc/FAQ.html
ApacheWeek at http://www.apacheweek.com

Some useful information is also available from the comp.infosystems.www.servers.unix newsgroup.

Mac OS X Server 1.x: Peer or Gateway in NetBoot Server

This article describes the difference between Peer or Gateway in NetBoot Setup Assistant.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

This information is covered in the "Setting Up Your NetBoot Server" section of the Mac OS X Server Install Manual. Choosing between Peer or Gateway depends on the configuration of your network. For example, a network administrator might want to connect both the Mac OS X Server and the NetBoot clients directly to a router on a single subnet. In this configuration, the administrator would choose Peer in the NetBoot Server Setup Assistant because the Server is Peer of the NetBoot clients.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Using Another BootP Server On NetBoot Network

Since the Mac OS X Server's NetBoot services use vendor specific enhancements to BootP in order to boot Mac OS clients, what happens to the clients if another BootP server is on the same network?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

NetBoot Server dynamically adds NetBoot capable computers to the NetInfo database based upon the vendor specific formatting in their BootP packets. NetBoot clients will take whatever BOOTREPLY it receives first. Therefore, other bootp and DHCP servers must not reply to the NetBoot client, in order for NetBooting to work successfully. If BootP services are desired for non-NetBoot capable machines for purposes other than NetBooting this can be facilitated by adding the client machines hardware Ethernet address to NetInfo via the NetInfoManager on Mac OS X Server.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Using As An AppleTalk Seed Router

This article tells why you would want to allow my Mac OS X Server to be an AppleTalk seed router.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you use more than one port on your NetBoot server, you need to be sure AppleTalk is in routing mode. There must be a seed router for every port that's connected to a subnet. The seed router can be the NetBoot server or an AppleTalk router.

If the NetBoot server is the seed router for a subnet, you must enter valid AppleTalk network numbers when you use the NetBoot Server Setup Assistant. It is important that you enter the correct numbers because the NetBoot Server Setup Assistant cannot check to see if the numbers are valid. If you enter the wrong values, AppleTalk won't startup.

If AppleTalk doesn't start up (You can check by using the ProcessViewer.), you can set up the NetBoot server so that only one port is used. Once you obtain the correct network numbers, you can set up other ports.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Macintosh Manager 1.0 Client Requirements

Will Macintosh Manager1.0 client software be available for pre-iMac computers? If so, what are the requirements for the clients?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Yes. The administration workstation requirements are as follows:

- Mac OS version 8.5 or later
- AppleShare Client 3.8.2 or later
- 800 x 600 resolution display or better
- 16 MB physical RAM (not virtual memory)
- 2 MB hard disk space (Additional space required on server for databases and preferences possibly up to 4 MB)
- Ethernet network

The client workstation requirements are as follows:

- Mac OS computer 68040 processor or later
- Mac OS version 8.1 or later
- 8 MB RAM (physically installed, not virtual memory)
- 2 MB hard disk space
- Appearance control panel 1.0.1 or later
- Ethernet networking set up

Published Date: Feb 18, 2012

Mac OS X Server 1.x: NetBoot Product Description

NetBoot Server is a collection of Mac OS X Server processes that allow for computers with ROM in RAM such as the iMac and Power Macintosh G3 Blue & White to boot from a remote volume.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The following are features of NetBoot:

- Single point of administration-You can use NetBoot software to manage all computers connected to the NetBoot server.
- Personal desktop-Users can log in to any computer connected to a NetBoot server and have the same Macintosh user experience.
- User authentication-Authentication provides a way to control who can log in to the computers connected to your server.
- Access control-You can decide which network resources (such as printers and applications) and which features of the Mac OS your users can access. Access control helps you to maintain desktop and network security.

A NetBoot network needs three types of software to make it work properly: administration applications, server programs, and the client operating system. Administration applications are needed to set up and manage your NetBoot server. Some of these administrative applications run on the server, and others are used from a network-connected client. Server programs run on the server under the Mac OS X Server operating system. Some of these programs don't have a user interface. Although server programs are not necessarily visible from a graphical perspective, it is necessary to know what they are and how they work to understand how your NetBoot environment operates. (You can use Process Viewer to check the status of a server program). The Mac OS used by client computers is downloaded from the server when a client computer starts up. The client Mac OS stored as a single image on the server. Every client computer uses the same Mac OS image. Management of this image can be used to administer all NetBoot clients.

Macintosh IIfx: Xerox 7650 Scanner Termination (11/94)

I have a Macintosh IIfx with HD80 SC and 4MB RAM (Quantum) running System software 6.0.5.

The Macintosh alone is functioning perfectly, but as soon I put on a Rank Xerox scanner 7650 and terminate with the black terminator, I am not able to start my system. The same scanner connected to a Macintosh IIcx, terminated with the old terminator, is functioning perfectly.

Do you have any suggestions?

This article has been archived and is no longer updated by Apple.
From your description, it sounds as if either the SCSI cables and terminators or the SCSI port on that Macintosh IIfx are bad -- or, much more likely, that there is an incompatibility between the Macintosh IIfx and Xerox 7650 scanner.

We contacted Xerox and found that this version of the scanner (having Macintosh and PC support) is distributed only by their VARs, and that Xerox will only support their VARs on this product. Because we were unable to get any assistance for you, we recommend the user contact the company that sold the scanner to see if there are new drivers or workarounds, and if not to escalate the problem through that organization and eventually to Xerox.

You also might try connecting another SCSI device or two on the same chain -- try in the middle or at the end.

Mac OS X Server 1.x: NetBoot Theory of Operation

When NetBoot software is installed on a server, images of the Mac OS and the Applications folder are copied onto its hard disk. The Mac OS image contains the Mac OS system software that each of your NetBoot clients needs to start up. The Applications image contains application software for your users. These appear as two separate hard disks on the desktop after the computer has started up.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Establishing a Network Connection

When a user turns on a NetBoot client computer, the computer broadcasts a message to find the startup server program. The startup server program responds by sending information (such as an IP address) the client computer needs to establish a connection to the NetBoot server. This information is entered using the Setup Assistant, which asks for a range of IP addresses that can be used by NetBoot computers. The NetBoot server keeps track of the client's hardware Ethernet address, and associates it with the IP address and other information in a table. Each time the client starts up from a NetBoot server, this table is referenced to ensure the client receives the same IP address and other information at system startup time. Addresses in the NetBoot range are therefore not recycled when a computer shuts down. They are stored in the table for use when the computer starts back up. Be sure to include extra addresses in the range you specify for additional clients on your network, as addresses are reserved for each client by the association between the Ethernet adapter address and the assigned IP address. Once a connection is established between a client computer and the server, portions of the Mac OS ROM image are copied from the server to the client computer's memory. This is done using the Trivial File Transfer Protocol (TFTP).

Note: The Mac OS ROM file must be present for NetBoot clients to start up successfully. When you use the installer, the Mac OS ROM file is installed on your disk. Be sure not to move or delete it. If you should add newer computers to your network over time, this file may need to be updated with a new ROM file to be compatible with your new computers.

Next, the Mac OS ROM image that was copied to the client computer's memory connects to the image of the Mac OS and opens the System file. You see an icon on the screen indicating that the Mac OS is starting up. This is accomplished by a minimal Apple File Protocol (AFP) client (AppleShare-type) contained in the Mac OS ROM and stipulates that there must be an AFP server running on the Mac OS X Server used as the NetBoot server.

NetBoot Process

- NetBoot client is turned on, Open Firmware (OF) net-boot begins transmitting BOOTP requests
- BOOTP server (bootpd on Mac OS X Server) receives request and looks for a host entry with the client's hardware Ethernet address
- If no entry exists, the server creates a new client identity:
    - Finds an available IP address on the client's subnet
    - Assigns the client a unique number i, range 1..n
    - Creates an AFP login account
    - Creates a new host entry
- Once an identity is established, the server: Creates an empty copy-on-write disk image file shadow of the system disk image created the first time and when size of shadowed file changes
- Places startup parameters into a BOOTP reply, sends it to client
- Open Firmware client receives BOOTP reply:
    - Stores the reply in the Open Firmware tree
    - Configures itself using the IP parameters in the reply
    - Downloads the startup file, Mac OS ROM, using TFTP
    - Passes control to Mac OS
- Mac OS retrieves BOOTP reply from Open Firmware tree
- The "network block driver" initializes itself using information in the reply:
    - Configures its IP stack
    - Logs into the AFP server using the AFP login identity
    - Connects to the system disk image copy-on-write and the applications disk image read-only
- The remainder of Mac OS starts up as usual
- Open Transport stack configures itself using BOOTP

NetBoot Disk Image Files

- NetBoot Server provides the client with three disk image files by default:
    - System read-only system disk image
    - Applications read-only applications disk image
    - System_s read/write system disk shadow of System

System and Applications disk images are shared by all NetBoot clients. Each client gets its own shadow system disk image-an empty image file the same size as System-created by the BOOTP server when the client starts up. Files written to the System image are written to the shadow file and are therefore not maintained when a client is restarted.

These images are stored on the Mac OS Extended format (HFS Plus) partition of the NetBoot server. If there is more than one HFS Plus partition on the server, the shadow images created for NetBoot users are automatically distributed between all HFS Plus volumes with available space.

Each NetBoot client's shadow image takes up the full system disk image space for a short time. Prior to starting up the shadow image size decreases in size and increases as needed.

There are two ways to start up a computer from a NetBoot server:

- Open the Startup Disk control panel and click NetBoot HD.
- Press and hold the "N" key as you start up the computer.

Mac OS X Server 1.x: Macintosh Management Overview

Macintosh Management software provides the means for easy administration of Macintosh computers in a variety of environments, while offering users the privacy of their own personal workspace.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The software provides desktop security by controlling which network and system resources users can access. Administrators can protect the System Folder and Applications folder.

Options can be set to promote password security, startup security, and that prevent users from reconfiguring the system or using unauthorized applications.

User accounts and workgroups can be managed from any computer connected to the server. Once the network is set up, there is very little daily management.

In school environments, teachers can distribute and collect assignments through the network. A teacher can also make available network resources, applications, and CDs that promote teaching objectives for his or her class.

To simplify maintenance, Macintosh Management stores the settings defined by the system administrator in one location accessible by all the computers on the network.

Macintosh Management requires an Apple File Protocol (AFP) server that is also running Macintosh Management server software for the storage of its databases. All the computers using Macintosh Management software must be connected to a network.

The maintenance of the data is handled by an administration application called Macintosh Manager. The application can reside on any Macintosh computer on the network including the NetBoot server. The Macintosh Management software can also control the administration workstation, but this is not a requirement.

The workstations require software that enforces the controls set forth by the administration program. This software is known as the client software.

At a minimum, a working configuration contains one AFP server, one Client/Admin workstation on an Ethernet network.

Mac OS X Server 1.x: NetBoot System Requirements

This article outlines the system requirements for NetBoot server and client.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Server

- Mac OS X Server
- 100BaseT Ethernet network (requires Category 5 cable)
- 750 MB hard disk (HFS), plus additional disk space per client, depending on usage - additional HFS drive space depending on usage.

Client

- iMac or Power Macintosh G3 Blue & White or later CPU
- 32 MB RAM or more
- Ethernet Network (10BaseT switched, or 100BaseT)

Mac OS X Server 1.x: Macintosh Manager System Requirements

This article outlines the system requirements for Macintosh Manager's server, administration workstation, and client.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Server

You can install Macintosh Manager software on a server that has Mac OS X Server installed.

- Mac OS X Server
- 1 MB RAM in addition to Mac OS X Server requirements
- 500 KB disk space (on HFS volume)
- Ethernet network

Administration Workstation

- Mac OS version 8.5 or later
- AppleShare Client 3.8.2 or later
- 800 x 600 resolution display or better
- 16 MB physical RAM (not virtual memory)
- 2 MB hard disk space (Possibly up to 4 MB additional space required on server for databases and preferences)
- Ethernet network

Client Computer

- Mac OS computer with a 68040 processor or better
- Mac OS version 8.1 or later
- 8 MB physical RAM (not virtual memory)
- 2 MB hard disk space
- Appearance extension 1.0.1 or later
- Ethernet network

Mac OS X Server 1.x: Macintosh Manager Versus At Ease 5.0

In Macintosh Manager for Mac OS X Server, some features of At Ease 5.0 have been removed, while others have changed. This article describes the most relevant of these changes.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Removed

1. Workstation Access List - In At Ease 5.0, each workstation had to be added to an "authorized" workstations list in order to use the server. If the workstation was not in the list, then it would not be able to run. This has been removed to eliminate the need to add workstations.
2. Web Access
3. Guardian Passwords - Guardians have been removed from Macintosh Manager. This was a concept that was mostly useful with the web access feature of At Ease 5.0.
4. Clues - In previous versions of At Ease, the administrator was provided a text string to be used as a clue to their passwords. With security becoming an increasing concern, this has been removed.
5. Attach Sounds - In all prior versions of At Ease, the administrator could attach sounds to the items that appeared on the brown panel in the Panels environment. These sounds would play when the mouse was passed over the button for an item with an attached sound. The new panels environment of Macintosh Manager does not support this feature.
6. Prevent users from accessing the hard drive by booting from a floppy or other removable media.

Changed

1. Finder Environment - The unrestricted Finder environment used to be a way of "turning off" At Ease. Macintosh Manager still supports this environment, but the user is actually logged into At Ease, which means user preferences and limited security will be permitted in this environment. This includes access to the user's documents folder, themes, volumes available at login, desktop printers, and application preferences. The system access environment is similar to the Finder environment in At Ease 5.0.
2. Special Folders - Special folders are a way of customizing certain folders on workstations to have a specific set of privileges. For example, on Machine A, which might be the "teacher station" in normal use, you might want one folder that exists here to contain items that only a certain workgroup could access (like, maybe, the Teacher workgroup). The special folders feature has been pared down to include one folder per workgroup.
3. Panels - The Panels environment has been updated and rewritten primarily to be more consistent with new visual aspects of the Mac OS.

Mac OS X Server 1.x: NetBoot Installation and Setup

This article provides an overview of the installing and setting up NetBoot Server on Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Planning Your Setup

Decide which HFS Plus volumes the NetBoot server should use:

- Determine network port configuration.
- Gather network information.
- Decide how server's Ethernet ports will be used.
- Determine configuration for each port.
- Choose an AppleTalk machine name.

Mac OS Extended (HFS Plus) Volumes Configuration Tips

- You must select at least one HFS Plus volume.
- The NetBoot Server software can load balance hard disk usage across several physical disks. Selecting multiple logical volumes that all reside on the same physical disk does not improve performance. If you have several physical disks, select one volume from each disk to improve performance.

1. Gather Network Information
    - Identify all existing IP routers in your network. For each router you need to collect the following information:
        - IP address
        - Routing table
    - Identify all existing AppleTalk routers in your network. For each AppleTalk router, collect the following information:
        - Network number range(s)
        - AppleTalk zone names
2. Draw a diagram of the network topology.
3. Determine where the NetBoot Server is to be connected to the network.
4. Decide How Server's Ethernet Ports Will Be Used
    - One port is used to connect to the existing network, we'll call it the Internet Port. The Internet Port is optional, but without it, the NetBoot clients will have no conduit to the Internet. Usually Ethernet port 0 (built-in). Usually 10BaseT is sufficient.
    - One or more of the remaining ports are used to connect the NetBoot clients. We'll call these the Client Ports. Usually Ethernet port 1 and up. 100BaseT is required.
5. Determine if server will also function as a Macintosh Manager Server.

Setup Assistant

The following items appear at the root level of the CD-ROM install disc:

Figure 1, Root level of the CD-ROM install CD

The NetBoot Server Setup Assistant prompts the user to gather information needed to complete the setup process:

Figure 2, NetBoot Server Setup Assistant Introduction

The following prompt asks whether or not Macintosh Management features are desired. Running the Setup Assistant also represents the simplest way to remove Macintosh Manager functionality:

Figure 3, Macintosh Management Server prompt

On servers with multiple Ethernet ports (such as our Mac Server G3) more listings will appear. One of them must be selected for use with

NetBoot.

Figure 4, Ethernet Port Planning

The following dialog configures the NetBoot Server device to function as a gateway if necessary:

Figure 5, IP Routing for NetBoot Clients options

The following configures both Bootptab and NetInfo providing the range of IP addresses that from which NetBoot clients can start up:

Figure 6, IP address range configuration

Files Installed

Mac OS Volume (HFS) Pieces

Mac OS ROM - This image is copied to the RAM of the NetBoot client.
NetBoot HD.img - This image is mounted on a NetBoot client computer when it starts up. It contains the system software used by the client.
Application image - This image is mounted when a NetBoot client computer starts up. It contains the applications that came with your NetBoot Server Software for use by your NetBoot clients.
Administration folder - This contains Macintosh Manager software and Macintosh Manager Help. You use these applications from a client computer connected to the server when you need to administer your Macintosh Manager configuration (Macintosh Manager auto connects to the server).

UFS (Mac OS X Server) Volume Pieces

- Admin framework
- Network preference panel with BootP support
- Startup server (BootP)
- AppleFileServices program (this program can only share items on HFS and Mac OS Extended Partitions, and is located in /usr/sbin directory)
- Macintosh Manager Server (located in the /usr/sbin directory)
- NetBoot Server Setup Assistant (located in the /System/Library/Assistants directory)
- HDNamer (Accesible via the Apple Menu)

HDNamer - A Mac OS X Server application that allows you to name your HFS volumes.
DiskFirstAid.app - This is a Mac OS X Server application that repairs your HFS volumes. Equivalent to Disk First Aid version 8.1 (from Mac OS 8.1). For additional repair options, run DFA 8.5 in the Mac OS environment or third-party disk repair utilities.
NetBoot Desktop Admin - The Applications and Macintosh HD volumes that you see when you log in to a NetBoot client computer are read-only volumes. You must use the NetBoot Desktop Admin software to make any changes to these volumes, such as installing applications for your users or changing the system configuration.
NetBoot Drive Unmounter - The "NetBoot Drive Unmounter" extension removes the internal hard disk from the desktop on a Macintosh booted from a NetBoot server during the startup process. This would be useful if the administrator of a Netboot server decided that access to the internal hard drives for a group of Macintosh computers should be prohibited. This may be desired to force users to store all data on the server, or to keep users from copying applications or files onto the internal drives of NetBooted computers. With this extension installed, the internal hard disk does not appear on the desktop, nor is it available in Open/Save dialog boxes.
Apple Secure Compression - Application which compresses and encrypts Mac OS files. Runs under Mac OS.

Mac OS X Server 1.x: Macintosh Manager Installation and Setup

This article describes the installation and setup of the Macintosh Manager on Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Macintosh Management Server

Macintosh Manager software works in conjunction with AppleFileServer (AFP) server software. The AppleFileServer is a server process that Macintosh Manager uses to communicate between the client computer and the Macintosh Manager databases.

Macintosh Management server provides the following services:

- Authenticates the administration user to the administration application.
- Returns login information to the workstation in order to allow the workstation to login to the server.
- Tracks the current login status of each client workstation.
- Provides some maintenance and setup functions of the AFP server.
- Provides AFP status information.
- Mirroring of the Macintosh Management and AFP databases.

Installing the Macintosh Management Server Software

The Macintosh Management server software is preinstalled on the Macintosh Server G3 computers shipping with Mac OS X Server preinstalled.

If you purchased Mac OS X Server software as a standalone package without hardware, you need to install NetBoot server software. NetBoot server software is on a separate CD that comes as part of the software package. You must install NetBoot server software on a computer that already has the Mac OS X Server software installed and set up. The Macintosh Management software is installed as part of the NetBoot server installation.

For complete instructions on installing the NetBoot Server software, see:

60085 "**Mac OS X Server : NetBoot Installation and Setup.**"

The NetBoot Server Setup Assistant guides you through the steps necessary to set up the software. To learn more about each step, click the Tell Me More button in the window. If you need to change any setup information in the future, you can use the NetBoot Server Setup Assistant to make changes. In Setup Assistant, you must select the option...

Figure 1, NetBoot Server Setup Assistant

Server Automatic Setup

All setup and configuration of the Macintosh Management server for clients access is done automatically. A sharepoint on the HFS+ partition is created on the server called "Macintosh Manager". This folder will hold the documents folder and the Macintosh Managers Items folder. An AFP User named "Macintosh Manager User" is created in the NetInfo database and a password generated. The user permissions are set to read and write to the sharepoint.

Figure 2, Macintosh Manager server contents

Tip: If the Macintosh Manager User is mistakenly deleted from the NetInfo database it will be regenerated when the server is restarted.

Tip: The Macintosh Manager User Password is dynamically reset every time the server process is started. Only the Macintosh Manager software knows it.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: Macintosh Manager Client Installation and Setup

This article provides an overview on the installation and setup of Macintosh Manager client software.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Workstation Setup

The workstation is pretty much self-configuring, since the administration program handles all the settings for the workstations and users. The only thing that you may need to do is to locate the Macintosh Management server.

If you are on an AppleTalk network, the workstation attempts to locate and connect to the first Macintosh Management server it finds in the local AppleTalk zone. If it finds one, the login dialog appears.

If the server it found was correct, you can log in with a user name (and optional) password, assuming that this information was previously specified in the admininstration application.

If the server it found wasn't correct, you can use the Server popup menu to select either another server in the same AppleTalk zone, or use the Other menu to bring up a dialog box that asks you to locate the server, either by AppleTalk or by IP.

Once the server has been located, the login dialog box reflects the new server's information.

The user can change the server location only as long as the computer has never been successfully logged into a Macintosh Management server.

Holding down the Shift key at startup does not bypass Macintosh Management, though you may be able to go to the Finder if no administration passwords are known, or if you enter a global administration password when asked. This is true for NetBoot clients as well.

In all environments, the File menu contains a Quit menu command to allow the user to logout (back to the login dialog).

User Environments

Before users can have access to the computer they must be authenticated by the system. This is done through the Login screen.

Figure 1, Macintosh Manager Login screen

Panels

The Panels environment provides a simple and easy to use interface, with large one-click icons that make it easy for the younger child. Buttons are now icons, similar to what you might find in a browser window (you click them once to "open" them). Because the panels environment does not show (or normally give) access to the client's hard disk, this environment can also be used to limit access by individuals to only those programs and files that they should have access to.

Figure 2, Panels environment

Restricted Finder

The Restricted Finder environment is a secured Finder environment that gives users access to the Finder, but imposes many default restrictions on the user. This environment is used to help protect workstations, while still giving the user access to the standard Macintosh desktop. In general, users are restricted to not being able to write to any location on the local volume except for their own documents folder.

Figure 3, Restricted Finder environment

Finder

The Finder environment imposes little or no restrictions on the users. Its primary purpose is to give users the virtual desktop experience. You can, however, protect the System Folder and Applications folder.

System Access

While not a true environment (that is, it can't be selected as an environment by the administrator but instead is given automatically to every global administrator), logging into this environment is equivalent to "turning off" Macintosh Manager. That is, when a user logs into a System Access environment, it is very similar to starting up the client workstation with Macintosh Manager off, gaining immediate access to the Finder.

The System Access environment is automatically granted to all global administrators, and can be optionally given to any other user as well.

Installing Workstation Software

For a workstation to be controlled by Macintosh Management software, the client software must be installed. The workstation software is preinstalled in the Mac OS image for Mac OS X server NetBoot clients.

To install software on a local-startup computer, follow these steps:

1. Start up the computer you want to install the software on.
2. Use the Chooser to mount the NetBoot server volume. When you log in to the server, use any user name and password that has read access to the NetBoot server volume. For example, you can use the name "Administrator" and the password you set up for the Administrator of the Mac OS X Server.
3. Locate the Macintosh Manager Installer folder and open it.
4. Double-click the Installer icon.
5. Follow the onscreen instructions to install the appropriate software.

Once the software is installed, the computer restarts automatically.

The components of the client software are:

- MM Client Panels
- MM Client Finder Plugin,
- MM Client Login
- MM Client Startup.

Workstation Startup

When a client netboots it immediately looks for a Macintosh Management server in the local AppleTalk zone. If it is successful it brings up a login dialog box.

If you have not configured any users or administrators at this point you can log in as Administrator using the password you set up for the Administrator (root) account on the Mac OS X Server. You can also log in to the Macintosh Management server as any Apple File Services user with the appropriate privileges.

Keeping in mind this is the first time the system has been used, the initial login gives the user full system access.

Mac OS X Server 1.x: Macintosh Manager Theory Of Operation

The Macintosh Manager is designed to set up and configure the Macintosh Management Server and its databases. The Macintosh Manager is used to create user accounts and workgroups, and to set up global, workstation, and server options. The options you set depend on the purpose of your network, the experience level of your users, and the security needs of your organization.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

How It Operates
When the Macintosh Manager application starts up, it checks to see if it has administered a Macintosh Manager server previously. If it finds that it has, through the Macintosh Manager Prefs, it attempts to automatically connect to that server, either using AppleTalk or IP.

However, if this is the first time (that is, no Macintosh Manager Prefs file was found), it first tries to use AppleTalk to locate any registered Macintosh Management server in the local AppleTalk zone. For a server to be registered, it must be running the Macintosh Management Server software.

If the Macintosh Manager cannot find a Macintosh Management server automatically, a dialog box appears asking the administrator to locate the server. The server can be specified as either an AppleTalk entity, or if you change the Find: popup menu, you can specify an IP setting; either an IP number, or a registered domain name address.

Once the Macintosh Management server has been located, the authentication dialog box is displayed. There are two primary ways of authenticating to the Macintosh Management server:

1. By entering the Macintosh Management server as root or Administrator (an alias of root) and password, or
2. By entering a valid Macintosh Manager global or workgroup administrator name and password.

If this is a first time case, only option (1) works, since there are no Macintosh Manager users assigned.

After proper authentication, the Macintosh Manager checks to see if the AFP server is running. If it isn't, the program goes directly to the Server pane, allowing the user to activate the AFP server, which is a requirement for adding users and workgroups. If the AFP server is already running, the application instead goes directly to the Users main panel.

A properly set up Macintosh Management system contains users, workgroups, and membership assignments (for example, attaching users to one or more workgroups). Various settings determine the privileges that a user gets.

Locating the software
The Macintosh Manager software can be found in one of two places. You can copy it to your administration workstation following the steps below or you can install it from the Macintosh Manger Install disk image. It is not preinstalled on the Mac OS or Application images mounted by NetBooted machines.

Follow these steps to locate the software and copy it to the administration workstation:

1. Connect to the Server as administrator and enter the server's root password.
2. Locate the Admin folder.
3. Copy the folder to your local hard disk or desktop.
4. Unmount the server volume by dragging it to the Trash.
5. Double-click the Macintosh Manager. If there is one Macintosh Management Server in the same zone, the login window opens.

Type the same user name, administrator, and enter the administrator password.

User names are case sensitive, but since "administrator" and "Administrator" are aliases of the user "root" both names work.

If a Macintosh Management server cannot be located, a dialog box appears asking you to find the server. You can find the server through AppleTalk or IP.

Configure User Environment
You need to configure at least one user and workgroup before workstations running the client software can access the Macintosh Management server.

Macintosh Portable: Details About the Idle and Sleep States 9/95

How much of the Macintosh Portable gets turned off at Shutdown, and how much gets shut down when you sleep? I am particularly interested in RAM disks.

This article has been archived and is no longer updated by Apple.
The Macintosh Portable has two power saving states: Idle (or Rest) and Sleep. Shutdown uses the same amount of energy as Sleep except when going into or coming out of a Shutdown state, when it requires more energy than Sleep for closing and saving files, and for bringing up the system and reloading the operating system when restarting. But while it is IN the Shutdown or Sleep state, the Portable will draw the same amount of electricity.

The Portable is considered idle after 15 seconds without any activity of any kind. The Portable is not considered to be idle if any of the following occurs:

- Any ADB routine other than routine monitoring of the bus
- Any I/O call to firmware (Read, Write, Control, Format, Status)
- Any change in the cursor (for example, the rotation of a hand in the clock icon)
- Any post-event call (for example, a call resulting from insertion of a disk)
- Any communication through the serial port

When the BatteryMonitor routine determines that the Portable is idle, it causes the CPU to insert 64 wait states into RAM and ROM accesses; this lowers the effective clock rate to approximately 1MHz. Interrupts continue to be processed at the full speed of the CPU.

After the Portable has been idle for the amount of time selected by the user, the BatteryMonitor routine puts the machine into the sleep state. When the Macintosh Portable goes into the sleep state, the Portable maintains full power to system RAM, video RAM, and the Power Manager IC.

The Power Manager IC stops the clocks to the SCC, the SWIM, and the ASC. By stopping the clocks to these devices, their power consumption is reduced to almost zero without requiring that they be reset, as would be necessary if all power were switched off. The Power Manager IC switches off power to the serial drivers, ROM, the flat-panel display, the ASC, the Sony sound ICs, the SCSI, and to a variety of pullup resistors and other components. The Power Manager IC sends a signal to the internal modem (if one is installed) that causes the modem to shut itself down.

After putting the rest of the system in the sleep state, the Power Manager IC does no processing except to monitor the 60HZ interrupt signal. Each time the 60HZ interrupt occurs, the Power Manager IC performs the following functions:

- It updates the real-time clock.
- It checks the wake-up timer to see if it matches the real-time clock.
- It checks the events that should return the machine to the operating state, such as a keystroke or a Ring Detect signal from the modem (when the modem feature has been enabled by the user).

The periodic functions take approximately 200 microseconds out of the 16.7 milliseconds between interrupts, so the Power Manager IC is inactive most of the time that the Portable is in the sleep state.

When the Power Manager IC determines that the wake-up timer matches the real-time clock or detects an event, it asserts the /RESET signal to the CPU, restores the clocks and power to other devices in the system, and then raises (deasserts) the /RESET signal.

Mac OS X Server 1.x: Setup Assistant Blocks Upper Case Characters In User Names

When trying to enter the name of a user in Mac OS X Server Setup Assistant, some letters may not appear in the dialog box as you type them. This article explains why.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

This is a result of the merging of two different operating environments. Mac OS X Server is based on Mach/BSD whose UFS (Unix filing system) is completely case-sensitive, while case sensitivity in Mach/BSD applications varies. Mac OS 8 file systems, including Macintosh Standard (HFS) and Macintosh Extended (HFS+) formats, are insensitive to case. That is, a UFS file system allows items named "Bob" and "bob" to exist at the same level, and sees them as separate items. Mac OS Standard- and Mac OS Extended-formatted volumes see "Bob" and "bob" as identical names.

In Mac OS X Server, if user "Bob" exists, and an attempt to create user "bob" is made, "bob" will replace "Bob". Because Mac OS X Setup Assistant also creates home directories for users it creates, it was determined that to force user names and home directories to lower case would help avoid interoperability problems with applications such as mail.

Mac OS X Server 1.x: DHCP Not In Initial Release

Mac OS X Server does not include DHCP in its initial release.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

DHCP has grown in popularity in recent years, and is now used widely.

Mac OS X Server does not implement DHCP in the initial relase of the product, but does fully implement bootp, of which DHCP is a superset. Bootp supports boot-time assignment of TCP/IP address, gateway router, subnet mask, and hostname over ethernet. Nameservers must be provided in /etc/hosts or configured manually. This dynamic assignment can be promiscuous, or restricted to particular MAC addresses ("Media Access Control", Ethernet hardware addresses).

Bootp is typically not routed, so as a rule, clients requiring bootp services must be on the same segment a bootp server.

Mac OS X Server 1.x: Why and Why Not Allow Remote Login

Mac OS X Setup Assistant network configuration includes a "Remote Login" panel that configures the system to "allow network access", but it has no "Tell Me More" button to explain why you might or might not wish to do this.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Remote Login in the Mach/BSD context means an ability to open a command line session from another computer on the network, using Telnet or other communications software. There are pros and cons to permitting this, or to disallowing it.

Security and administrative capability are the contesting issues here. Security is obviously stronger if the system doesn't even support remote command line connections, even though password access still applies. Environments where it might be considered particularly risky to allow remote logins would include systems connected directly to the Internet without a firewall; systems with critical financial, commercial, military or other confidential data; systems located in university or non-elementary school environments, or even in highly competitive business environments.

An available telnet connection, along with a non-root user account that is a member of group "wheel", enable detailed system administration and monitoring to be done remotely. This can be a huge asset, especially in the relatively rare event that the system's GUI interface ("Workspace Manager") should freeze, or keyboard and mouse become unresponsive. In such situations, the server may well be running and behaving in a normal manner as far as most users would be concerned, but without the remote login and with no console access, it can be pretty awkward shutting down the system or restarting it. Also, a telnet session can eliminate much of the need for console access; this is very handy if the computer is located in a remote or difficult location.

To allow remote logins doesn't inherently invite disaster. There are two layers of protection inherently involved: the normal username-password security, and the fact that on Mac OS X, the root (administrative) account doesn't directly allow remote logins; one must first telnet in with a less-privileged user account, and, if that user account is made a member of group "wheel", that connection will be allowed to "su" to the root account once connected. One must have the root password to do this, of course.

Almost any operation not involving graphics can be performed with a telnet command-line connection; in particular, text-based programs and utilities can be run; data drives can be dismounted and checked; files can be edited, copied, deleted, duplicated, or printed; best of all, though, the system can be shut down or restarted in a proper, orderly manner.

Thus, it is an important decision for the administrator to decide whether to forgo these capabilities in the interests of security, or not.

For further information, read the man pages on su and telnet.

Mac OS X Server 1.x: Why and When fsck Should Be "Forced" To Run

Occasionally a Unix-style operating system may find itself shut down in such a manner that it is unable to write cached date or directory information back to disk. Under rare circumstances, one or more of the system's volumes may not have been properly flagged as "dirty." Because Unix-style operating systems fail to see that such a file system needs repair, autorecovery fsck fails to run before mounting the drive. Sometimes the damage may be such that the volume fails to mount, which brings the matter to the administrator's attention. However, if the volume mounts successfully and the system is put back in service without precautionary maintenance, continued writing may cause additional damage.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Fortunately, these occurrences are quite rare, but the savvy user is well advised to learn in what circumstances such a situation is prone to occur, and intervene appropriately as a precaution. In the case of servers, it is always best to assume that any disorderly shutdown can lead to such a situation.

Review of a great many support calls reveals that most of these situations stem from storm or other power outages, brown-outs, power supply failures, kicked power cords, shutdowns or restarts forced by an operator from front-panel buttons or keyboard, or unresponsiveness caused by hardware failure. All of these are very sudden events. A brownout or a spike caused by a nearby lightning strike seems often to be the cause of the more severe situations.

If performed promptly, recovery of these unflagged dirty file systems can be routinely successful, but because the dirty flag isn't set, the system itself does not recognize the need for autorecovery. Therefore, the system administrator must know when to do routine manual maintenance for any of the improper shutdown situations described. It is especially important for servers because the data of many users may be at risk.

A typical Unix-style system has one root filesystem that contains the system software, and may have one or more data volumes mounted within this root filesystem.

If a system is believed to have suffered a traumatic shutdown, the first step in recovery is to startup partially to "single-user" mode, which gives a command line shell interface that can perform a file system check "fsck" on the system file system before it is mounted. For more information on this process, see the following article:

Article: 24501 "**Mac OS X Server: Why, When, and How to Run fsck for File System Maintenance.**"

Here are a few **very** important notes about using fsck in these situations:

1) If the default Unix-based partition is completely full, or almost completely full, it may be necessary to delete a few files before there will be enough scratch space on the disk for fsck to write recovered or temporary data.

2) If the filesystem isn't flagged "dirty," the usual fsck command believes the filesystem to be clean, and drops back to the command line without doing maintenance. To circumvent this and force the fsck utility to run, add the "-f" flag to the fsck command:

```
fsck -y -f
```

The root (boot) file system is assumed.

3) Any time that fsck makes any changes whatsoever to the drive, the final line before the prompt returns states: "***** FILE SYSTEM WAS MODIFIED *****." If your file system check ends with such a message, it is important that the check be run again until this message no longer appears. This is because repairs that allow the system access to parts of the file system that were unintelligible before may unearth previously undetected damage.

4) If repairs cannot be made, or if an error is presented regarding difficulties reading the file system's superblocks (the master table of pointers to directory elements which begins at block 8 of the volume), fsck can be directed to use one of the alternate copies of the superblocks. The first of these is block 16, on most Unix-style systems. Thus, to recover using a superblock mirror, the command becomes:

```
fsck -y -f -b16
```

Note that because the original default superblocks at block 8 is re-written from the mirrored data at block 16, the message "***** FILE SYSTEM WAS MODIFIED *****" occurs. Therefore, it is necessary to run fsck again, but without the redirection to a superblock mirror. Only the first pass of fsck should be used with the -b flag, because once this is done, the default location has the same information as the mirror.

5) In the very, very unusual event that the superblocks at location 16 are also illegible, one may suspect that extensive damage has occurred, but the file system may still be salvageable if other superblock mirror locations are readable. To learn where other superblocks are located, use the "disk" command:

```
disk /dev/rhd0a
disk> scan
```

Disk scans the partition for superblock mirror locations, listing each as it is found.

To exit the disk utility, type "q" or "quit." For a summary of disk commands, type "?". For more information about the disk utility, which can initialize, partition, and query a disk in many ways, type the following command at the prompt:

```
man disk
```

6) Whether the -b flag is used or not, if fsck is run three to five times and repairs are still being made, or especially if the same repairs are made over and over, one may conclude that either the data is truly damaged, or that there is a hardware fault. This may include worn media, damaged media, a frayed, cracked, or loose data cable, or a bad controller. If it is severe,

7) Have room on disk (df)

8) lost+found?

9) When fsck runs, it echoes to screen each problem it discovers, asking if you want it fixed, repaired, or salvaged, and automatically answering "y" if you entered the -y flag on the command. Errors such as

```
cannot stat /dev/rhd0a
```

or

```
cannot determine file system type of /dev/rsd0a
```

could mean that you have entered the command incorrectly (targeted a drive that doesn't exist, isn't powered up, or isn't a UFS or Mac OS Extended (HFS+) file system type. These errors may also mean exactly what they say: the disk may be damaged, or for other reasons may not be communicating properly. Cables, connectors, and SCSI termination (if applicable) should be reviewed carefully, especially if recent changes have been made to storage subsystems.

10) It is important to bear in mind that an improperly terminated SCSI system can behave properly for a while, only to become suddenly stubborn. Make no assumptions here unless you enjoy reformatting and reconfiguring systems. With internal SCSI devices, it is especially important to verify that termination jumpers are removed from all but the last device, because raw mechanisms are almost always terminated when received.

11) Once fsck runs without error, you may continue your use of the computer with one of the following commands:

`exit`	(the single-user shell)
`reboot`	(restarts and proceeds through a normal startup)
`shutdown`	(powers the computer off)

For additional details about fsck, enter "man fsck" at the command prompt or see article 24501: "**Mac OS X Server: Why, When, and How to Run fsck for File System Maintenance.**"

Mac OS X Server 1.x: NetBoot Disk Images Have Extra 4 KB of Data

If you run Disk First Aid on the NetBoot disk images, it reports that files are damaged and can't be repaired.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The NetBoot disk images shipping with the Mac OS X Server have an extra 4 KB of data at the end of their data forks. This makes Disk First Aid complain about them. It does not affect the data in any way. Version 1.1 of NetBoot Desktop Admin automatically repairs the images.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: How AppleFileServer Starts

This article describes how Apple Files Services starts under Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The startup process for the AppleFileServer begins with AdminWebServer. AdminWebServer is started at boot by inetd if the server is configured for AppleFileServer. The configuration is checked and AdminWebServer started with the script '/etc/startup/1600_AppleShare' which checks for the configuration in hostconfig as well as NetInfo.

```
cat /etc/startup/1600_AppleShare
    #!/bin/sh

    . /etc/rc.common

    CheckForNetwork

    if [ "${NETWORKUP}" = "-NO-" ]; then exit; fi

    ##
    # Start the AFP Server
    ##
    if [ "${AFPSERVER:=-NO-}" = "-YES-" ]; then
        ConsoleMessage "Starting AppleShare server"

        echo "Starting the AdminWebServer server"
        /usr/sbin/AdminWebServerctl start
    fi
```

If AppleFileServer's NetInfo property is set to start AppleFileServer at startup, the AdminWebServer server starts a single process of AppleFileServer (the "parent process") which does not serve files. That single parent process generates the second process (the "child process") which actually performs the file serving.

```
ps ax |grep AppleF
 632 ?  I     0:00 AppleFileServer /tmp/afpserver_PIPE
 639 ?  S     0:00 AppleFileServer /tmp/afpserver_PIPE

ps al 632
      F  UID   PID  PPID CP PRI BASE VSIZE RSIZE WCHAN STAT TT  TIME COMMAND
      4    0   632     1  0  10   10 6.19M  368K     0  I   ?   0:00
AppleFileServer /tmp/afpserver_PIPE

ps al 639
      F  UID   PID  PPID CP PRI BASE VSIZE RSIZE WCHAN STAT TT  TIME COMMAND
      4    0   639   632  0  10   10 38.6M 2.05M     0  S   ?   0:00
AppleFileServer /tmp/afpserver_PIPE
```

To administer the AppleFileServer, the AdminWebServer server is used again. Connecting to the server on port 311 (http://servername:311) connects to the AdminWebServer server (using a FastCGI). The settings added by AdminWebServer, along with other configuration settings for the AppleFileServer, are stored in the NetInfo database.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: What‘s The Group "macos"?

This article tells what the group "macos" in Mac OS X Server is.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Users set up through the AdminWebServer for Apple File Services belong only to the default group: "macos". This group is also the default group for files created by AppleFileServer only users.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Using the HFS Plus Volume With Apache

This article tells how a directory in the Mac OS Extended Format (HFS Plus) volume can be used by the HTTP Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Some administrators may wish to configure their Mac OS X Server for Web creation by Apple File Services only users. Because Apple File Services serves only from the Mac OS Extended format (HFS Plus) volume, the administrator must make directories on this volume available to the HTTP server in one of two ways:

1. The HTTP server may be moved to the HFS Plus volume (configured in SetupAssistant or changed in the Network Preferences). Because HFS Plus does not have some of the inherent security features of UFS, administrators should take precautions with this configuration.
2. Directories on the HFS Plus volume may have links in the HTTP server's directories. Notice that the setting in the /Local/Library/WebServer/Configurations/apache.conf file that allows the HTTP server to follow these links is in the OPTIONS for the specific directory. Use OPTION followsymlinks to enable the HTTP server to access the HFS Plus directories. **Note:** This is also a type of security risk and careful consideration of access and privileges should be taken. (Remember that the HTTP server settings are only read when that server starts. Any changes to the .conf file requires restarting the Apache server.)

Published Date: Feb 18, 2012

Mac OS X Server 1.x: NetBooted Clients Unresponsive When NetBoot Server Stopped

NetBooted clients that have started up from a server become unresponsive when AppleFileServer is shut down.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The clients may appear fine until they attempt to access the system or any items from the mounted volume. Making the server available again does not allow clients to smoothly transition from one session to another. They must be restarted if the AFP server is restarted or brought down at any point.

To avoid client computer unresponsiveness, remember to shut down all NetBooted clients before shutting down or restarting the server, or when quitting the the AppleFileServer through Macintosh Manager or Remote Administration.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Preventing a Client From Binding to a NetInfo Server

This article tells how to change a computer's configuration so that it does not attempt to bind to a NetInfo server at system startup time.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

A client configured to bind to a NetInfo parent at system startup times out after a period of minutes if a NetInfo sever is not available. Depending on the number of interfaces, this may be longer on some computers. To prevent the client computer from attempting to bind to NetInfo, you can type this command while the computer is started up in single user mode:

```
liutil -destroyprop /etc/netinfo/local.nidb /machines/broadcasthost serves
```

Warning: the lituil command should only be used in single user mode. Otherwise, a NetInfo database that was open for use under multi-user mode could be rendered unusable.

Mac OS X Server version 1.2 does not include the liutil command. It is only available if the server has an earlier version of Mac OS X Server or if it was upgraded to version 1.2 with the upgrade CD.

Entering the lituil command with no parameters shows the proper syntax and parameters that liutil accepts.

LaserWriter: How to Change Page Types

This article has been archived and is no longer updated by Apple.

The selection of built-in 'page types' has been enlarged to include two European sizes. The height of the letter and legal page sizes has been slightly decreased because of memory constraints in the new software. Finally, the function of the 'note' page type has been generalized.

The LaserWriter includes buit-in device setup procedures for establishing any of seven standard page types:

1. letter

2. legal

3. A4

4. B5

5. lettersmall

'Lettersmall' is an imageable region 7.68 by 10.16 inches centered on an 85. by 11 inch page.

6. A4small

7. note

'Note' selects one of the above page types according to the paper tray that is installed. If the letter or A4 tray is installed, 'note' selects 'lettersmall' or 'A4small' respectively. If the legal or B5 tray is installed, 'note' selects 'legal' or 'B5'.
For the letter or A4 paper sizes, this has the effect of increasing all four margins to approximately 0.42 inch. The reduction in the imageable area frees up as much as 100,000 bytes of memory, which is added to the VM (Virtual Memory) and made available for PostScript programs.

Page 121 of the LaserWriter and LaserWriter Plus manual (copyright 1986, Apple Computer, Inc., manual number: 030-1296-B) describes the letter, legal, A4 and B5 pages sizes.

Mac OS X Server 1.x: About Mac OS X Server

Contents

Introduction
Backing Up and Restoring Your Mac OS X Server
AppleShare and Apple File Services Issues
QuickTime Streaming Server Preview Software
Obtaining Database Adapters for WebObjects
Selecting Ethernet Ports
Naming Users and Groups
Other Issues

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Introduction

This document provides information about your Mac OS X Server software that supplements the information in the Mac OS X Server Installation Manual. Read this document for information about known problems with this release and possible solutions. Additional information can be found in the following places:

- Read Me documents available in the System/Documentation/ReadMe/ folder
- Read Me documents in the Admin folder in the NetBoot installation volume
- the Help menu

For up-to-date news and compatibility information, see the Apple Support Web site at http://www.apple.com/support.

Note: If you are familiar with UNIX-based systems, you will find using your Mac OS X Server easier. Information in this document and the other Read Me documents included with your server assume you are familiar with this type of operating system.

Backing Up and Restoring Your Mac OS X Server

Your Mac OS X Server system uses a UFS format volume. You may also have Mac OS (Standard or Extended) format volumes on your Mac OS X Server. At present, to back up and restore volumes, you need to follow different procedures depending on the format of the volume.

Backing Up and Restoring Mac OS Format Volumes

To back up and restore Mac OS format volumes, you can use third-party programs such as Retrospect from Dantz Development Corporation. To use such a program, install the software in the Mac OS environment (open the Apple menu and choose Mac OS), then open the program and follow the instructions provided with the software.

Important: Retrospect does not back up permissions information for files and folders. If you restore a volume using Restrospect, you will need to set permissions again.

Backing Up and Restoring Mac OS X Server Format Volumes

For a sample script that backs up the UFS partition, please see article 60145: "**Mac OS X Server: UFS Backup Script**" The article contains a generic script; you may need to customize it for your specific needs.

AppleShare and Apple File Services Issues

AppleShare password security: When a client user logs in to Apple file services, the user's password is sent over the network in clear text form. Someone monitoring your network traffic could get the Administrator password, thus compromising your network's security. For information about updates to correct this situation, see http://www.apple.com/support.

AppleShare client software: To connect to an Apple file services volume from a client computer, you need to install the AppleShare client software, versions 3.8.2, on the client computer. This version is available in the Utilities folder on your Mac OS X Server installation CD.

Connecting to Apple file services using IP: If you want to connect to Apple file services from a client computer using IP, instead of AppleTalk, you need to enter the server's IP address in the Router box in the TCP/IP control panel on each client computer. To do so, open the TCP/IP control panel on the client computer, choose Ethernet from the "Connect via" popup menu and Manually from the Configure popup menu, then enter the server's IP address in the Router address box, as well as the other information required for the connection.

QuickTime Streaming Server Preview Software

This release of Mac OS X Server includes a preview release of the QuickTime Streaming server, which will let you deliver rich digital media over the Internet or intranets to any QuickTime-capable application. For information about updates for QuickTime Streaming, see the QuickTime Web site at www.apple.com/quicktime/.

Note: Telephone support is not available for preview software, such as QuickTime Streaming server.

Obtaining Database Adapters for WebObjects

Your Mac OS X Server includes WebObjects adaptors that let WebObjects applications connect to and retrieve data from OpenBase and flat-file databases. An adaptor for Oracle will be available soon. For information about availability of other adaptors, see the Apple Developer Web site at http://www.apple.com/developer.

Selecting Ethernet Ports

If you purchased a Mac OS Server G3 With Mac OS X Server, it includes a four-port Ethernet card. An illustration in "Connecting to an Ethernet Network," in Chapter 1 of Setting Up Your Macintosh Server G3, shows the four ports of the Ethernet card numbered 1 to 4 from left to right. However, the ports are numbered from right to left. Therefore, in the Setup Assistant or Network settings panel, Ethernet Card Port 1 corresponds to the port on the right while Ethernet Card Port 4 corresponds to the port on the left.

Creating and Changing Users and Groups

You should name users and groups on a Mac OS X Server using only the lowercase alphabetic characters (a-z), the numeric characters (0-9), and the underscore character. This includes users and groups you create for Apple file services using Remote Server Administration.

If you create a NetInfo user account on your Mac OS X Server, do not use a name that you plan to use for a Macintosh Manager user account. If you do, you will see a warning message when you try to create a user with that name in Macintosh Manager.

Remote Administration shows Administrator (root), Unprivileged user (nobody), and macos group. Do not change the names of these items.

NetworkManager lets you change the names and IDs of all user accounts and groups. Do not change the names or IDs of user accounts and groups with IDs less than 100.

Other Issues

- You cannot start up a Mac OS X Server from an ATA disk configured in Slave mode.
- You should not change the name of a volume used by NetBoot server unless absolutely necessary. If you do change the name of the volume, you will need to install the NetBoot server software again.
- You can customize the contents of your Mac OS X Server Apple menu by choosing Configure Menu from the Apple Menu. If Configure Menu is not available, open the AppleMenuOptions application directly from the Workspace Manager. The application is located in the System/Applications folder.
- The floppy disk driver supports MFM formats such as 1.44 MB and 720 MB floppies. At present, it does not support formatting and writing to GCR formats such as 400K and 800K. Therefore, GCR floppies are marked as Write Protected.

Mac OS X Server 1.x: About the Apache Web Server

This document describes issues with the Apache Web (HTTP) server provided with Mac OS X Server.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Recent changes

This release of Mac OS X Server includes version 1.3 of the Apache Web server. This version offers new features and slightly different usage. For example, Apache now opens properly with the apachectl command, rather than by using the apache command directly.

See the Apache manual (/System/Documentation/Administration/Services/apache/index.html) for Apache version 1.3 release notes and instructions.

Patches have been sent to the Apache Group so that versions of the Apache Web server after version 1.3.4 should build on Mac OS X Server without needing to port the software. For or more information, see http://www.apache.org/.

Apache now includes DSO support. For more information, see the "Dynamic Shared Object (DSO) Support" section later in this document. Apache headers needed for the compilation of loadable modules are now available in the Apache Framework.

Differences between Apache for UNIX systems and for Mac OS X Server

The location of files on Mac OS X Server reflects the structure of the Mac OS X Server directory, which extends the standard BSD filesystem conventions.

- Executables follow BSD conventions. You can find the Apache server executables (eg. apachectl) in /usr/sbin and tools (eg. htpasswd) in /usr/bin.
- The default server root is /Local/Library/WebServer, where you will find configuration files, server executables, logs, and the document root. This directory includes a basic server configuration when the system is installed to provide users with a good starting point.
- Apache's built-in icons and loadable modules included with this distribution are in /System/Library/Apache.

Known issues with restarting Apache on the Mac OS X Server

Due to an unimplemented feature of the dynamic linker, both soft and graceful restarts of Apache cause a significant penalty in memory consumption. See "Dynamic Shared Object (DSO) Support" below.

Graceful restarts are believed to cause Apache to become unstable and may cause the server to exit with an error message in the error log, such as "[warn] long lost child came home!" You should avoid graceful restarts anyway because of the DSO unloading problem. To avoid this problem, use the same workaround described in the "Dynamic Shared Object (DSO) Support" section next.

Dynamic Shared Object (DSO) support

Apache now loads its modules dynamically using dyld. This means that Apache does not need to be recompiled to add additional modules if the modules are compiled as dynamic modules. In addition, you can now disable code that you don't want linked into Apache simply by editing the server configuration.

To provide all the Apache features, all standard Apache modules are compiled into the Apache binary. However; you can selectively add and remove the modules you are interested in using. See the Apache documentation for details on developing, configuring, and using DSO modules.

Known issues with Apache DSO support

The dyld API allows runtime linking of executable files, but unloading these files is not implemented currently. Sending a HUP signal to Apache, which asks Apache to reload its configuration, causes Apache to attempt to unload its modules and then load them. The unload operation fails without notification but the load operation will succeed and will use any new symbols found in the modules, if any have changed. As a result of this, the process size will grow, consuming additional memory each time you soft restart the server in this way.

The commands `apachectl restart` and `apachectl graceful` attempt a soft or graceful restart, so both run into this problem.

The workaround is to always hard restart the server by stopping it, then restarting it using `apachectl stop; apachectl start`.

Tips for improving server performance

Move the document directory

Resolving pathnames can require a significant amount of time. If it's important that your server is able to deliver a large number of documents per second, then the default document root (`/Local/Library/WebServer/DocumentRoot`) may not be appropriate. If this is an issue, you may want to move your document root to the root of the filesystem, for example `/WebDocs`. For best performance, you may choose to mount a fast disk on the document root directory.

Disable any server features that you are not using

Avoid loading any modules that you don't need and disable any features which don't apply to your server usage.

Loaded modules require additional memory. (See "Dynamic Shared Object (DSO) Support" earlier.) and may add additional processing on some or all incoming requests.

If you need to maximize the performance of your Apache Web server, you may want to compile a version which sets compile-time settings to meet your needs. See the Apache documentation for more information on compiling your own server and suggestions on maximizing performace at compile time.

The official Apache distribution is available from The Apache Group, although the port to Mac OS X Server may not yet be integrated into the official distribution. Apache source code which compiles properly on Mac OS X Server may be available on the Developer ToolKit CD or from ftp.apple.com.

Using Mac OS format volumes with Apache

Because of the way in which Mac OS Standard (HFS) and Mac OS Extended (HFS Plus) format volumes handle uppercase and lowercase file names, you should avoid using these volumes to store your Apache document root. Apache may fail to operate as documented on case-insensitive filesystems. For example, access control checks may fail and compromise the security of your server.

You should also avoid locating your documents on NFS volumes. Doing so may significantly reduce the performance and reliability of your server.

Mac OS X Server 1.x: About Apple File Services

This document contains important information about using Remote Server Administration to administer Apple file services.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Browser compatibility issues

- Before logging in to Remote Server Administration from your browser, open Preferences and set the cache settings to Never (for NetscapeTM Navigator) or Always (for Internet Explorer).
- This version of Remote Server Administration is incompatible with Microsoft's JavaTM Virtual Machine in Microsoft Internet Explore, version 4.0.1 or earlier. Before using one of these versions of Internet Explorer with Remote Administration, open Preferences and set the Java virtual machine option to use Apple MRJ (Mac OS Runtime for Java). Make sure your computer has MRJ version 2.0 or later installed by checking the version of the MRJLib in the MRJ Libraries subfolder in your Extensions folder.
- Before using Remote Server Administration with European keyboards on non-localized Mac OS computers sold in the U.S., you must specify the appropriate font encoding settings in the Web browser preferences. For Internet Explorer, check the Language/Fonts settings in the Preferences. For a Netscape browser, check the Encoding settings.
- If you connect to your server through a proxy using Netscape Communicator, you may experience timeout problems and data may not be updated on the server. If you experience this problem, use a direct connection to the server. If you must use a proxy, talk to your proxy server administrator about enabling HTTP write access to the Mac OS X Server.
- If you are using Microsoft Internet Explorer with Remote Administration, you should set the preferred size of memory to at least 12 MB.

Issues with using Remote Server Administration

- To log in to Remote Server Administration, your user account must exist in the NetInfo database on the same server as the Apple file services. All accounts created using Setup Assistant, NetworkManager, and Remote Server Administration are stored in the local NetInfo database.
- You can only use 7-bit characters for administrator and user passwords. These are the standard ASCII characters which include control characters, alphabetic and numeric characters, and standard keyboard characters.
- Due to a limitation in Netscape Java, the Caps Lock key is not recognized to enter uppercase letters in a password. To use uppercase letters in a password, press the Shift key.
- If you are using Netscape Navigator or Netscape Communicator with Remote Administration, do not click Reload. If you do, you will need to log in to Remote Administration again. You may also need to log in again if you resize the browser's window.
- Do not use the browser's Back button to return to a page in Remote Server Administration. If you do, settings you have made in the page may appear to be different.
- The server access log (AppleFileAccess) is not turned on automatically. To turn on access logging in Remote Administration, click File then click Server Settings, select the Log Server Access checkbox, and click Save.
- For Internet aliases and group names, you can use only lowercase letters, numbers, and the underscore character.

Issues with Apple file services

Do not give your server the same name as any other AppleShare or Apple file services server on the same zone of the network. Remote Administration does not warn you if you do. However, users trying to log in to the servers may be unable to log in to the server they want to use. Check the server error log (AppleFileError) for information about this problem.

You can't change access privileges for removable media. You can share folders on the removable media, but files are read-only for everyone.

If you define more than a few hundred sharepoints on the server, some sharepoint names will not appear in the client's Chooser.

Folders created by guest users are owned by "Unprivileged user" (nobody). To reassign privileges for these folders, log in to the server computer Administrator (root).

Local host information for your server computer may not be saved in the local NetInfo domain if you use Setup Assistant to choose a connection to a NetInfo parent server then turn off the connection, for example by using the Network settings panel, and you have configured DNS manually without any DNS server addresses being specified and TCP/IP to get the host name and default router automatically using Bootp. If NetInfo domain does not contain the local host name, Apple file services will not start and any applications that use the local host name will fail. If this happens, open Setup Assistant and make sure you do not have your network services configured in this way.

If Apple file services does not start when you start up your server computer or when you turn on the service using Remote Administration, check the server error log (AppleFileError) for information about startup errors.

Issue with AppleTalk configuration

If AppleTalk isn't configured correctly, it will fail when you start your Mac OS X Server but you will not receive a message about the problem. If this occurs, AppleShare clients will not be able to locate the server in the Chooser and Macintosh Manager clients will not be able to log in to the server.

Note: Because Apple file services can use TCP, Remote Administration will show that the server is running and NetBoot client computers will be able to start up

If you experience these problems, be sure AppleTalk is configured correctly using the Setup Assistant and Network Settings control panel.

If you configure more than one port on your server computer to use AppleTalk, each port must be connected to a network with an AppleTalk router. If your server computer is acting as the router, make sure it is configured correctly and does not conflict with other AppleTalk routers on the network.

Issue with the AppleShare client software

If AppleShare client computers have Mac OS 8.5 or later and AppleShare client version 3.8.1 installed, files may be corrupted in some cases when users copy files to server volumes. To prevent this, install AppleShare 3.8.2 on all the computers installed with Mac OS 8.5 or later. AppleShare 3.8.2 is provided with the Mac OS X Server software.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: AppleShare Client 3.8.2 Read Me

Contents

Introduction
Requirements for using the software
Installing the AppleShare client software
Changes with AppleShare client software version 3.8.2
Using the new features of the AppleShare client software
Known incompatibilities and limitations

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Introduction

AppleShare 3.8.2 is the latest version of AppleShare client software. This document provides important information about using the AppleShare client software.

Requirements for using the software

- System software version 7.6 or later
- Open Transport version 1.1.2 or later

To use AutoRemounter on a PowerBook with AppleShare client version 3.8.2 on systems earlier than Mac OS 8.5, you should use AutoRemounter version 1.3, which is available in Mac OS 8.1. If you are using Mac OS 8.5, open the Energy Saver control panel and click Advanced Settings, then select the network connections options you want to use.

The version of the AppleShare client software you use depends on the version of the system software you have installed on your computer:

- For Mac OS 7.5.1 or earlier, use AppleShare Workstation version 3.5.
- For Mac OS 7.5.1 up to (but not including) version 7.5.3, use AppleShare Workstation version 3.6.5.
- For Mac OS 7.5.3 up to (but not including) version 7.6, use AppleShare client version 3.7.4.
- For Mac OS 7.6 and later, use AppleShare client version 3.8.2.

Installing the AppleShare client software

To install the AppleShare client software, double-click the Installer and follow the onscreen instructions.

The AppleShare Client Installer places the AppleShare Chooser extension in the Extensions folder (in the System Folder) appropriate for the localized version of the Mac OS installed on your computer.

If you want to connect to AppleShare servers using TCP/IP, make sure that the TCP/IP control panel is set up correctly.

Changes with AppleShare client software version 3.8.2

- Improves performance when connecting to a Mac OS X Server computer.
- AutoRemounter now recognizes the most recent PowerBooks.
- The client software works correctly with AutoRemounter version 1.3.
- Dialog boxes are centered correctly if you have more than one monitor.
- Aliases to servers mounted using an AppleTalk connection will not switch to a TCP/IP connection. If you want a server alias to open a TCP/IP connection, you must mount the server using TCP/IP then create an alias.
- You can now cancel when you attempt to log in to a server.
- The client software now provides a transport independent UAM (User Authentication Module) interface. This allows UAM plug-in modules to connect to servers using AFP over TCP/IP. Contact your UAM vendor for a new version of your UAM that works with this interface. Existing UAMs will still work.

Using the new features of the AppleShare client software

The AppleShare client software now automatically connects to a server using TCP if a user chooses an AppleShare IP file server that is set up for TCP connections. If you want to use AppleTalk to make the connection, press the Option key and double-click the name of an AppleShare IP file

server in the Chooser.

When you want to use TCP to connect to an AppleShare IP file server that does not appear in the "Select a file server" list in the Chooser, click the Server IP Address button. When you click the Server IP Address button, a dialog box appears in which you can type the DNS name (such as shasta.acme.com) or the IP address (such as 172.16.156.52) of the AppleShare IP file server .

If the AppleShare IP file server is on a computer behind a firewall, you can connect to it by adding a colon (:) and the TCP port number (the default is 548) to the IP address or DNS name.

Known incompatibilities and limitations

- If you have problems using AppleShare client software version 3.8 to connect to an AppleShare IP file server, use MacTCP Ping (available from Apple Computer) to make sure that you can ping the server computer. If you can't ping the server computer, there is a connectivity problem. Check the network cables and the configuration of the TCP/IP control panel.
- If a computer has Mac OS version 8.1 or earlier installed and a user connects to a volume on an AppleShare IP server using TCP/IP, AppleTalk must be active on the user's computer to make an alias to that volume.
- In AppleShare IP version 5.0, the Web & File Server uses a set of access privileges based on combinations of the original access privileges (See Files, See Folders, and Make Changes). The new privileges are Read Only, Read & Write, Write Only, and None. When you connect to an AppleShare IP file server volume and choose Sharing from the Finder's File menu, the dialog box that appears displays the original AppleShare access privileges. If you use the dialog box to change a folder's privileges to a combination of privileges that is invalid for the AppleShare IP file server, the file server automatically applies the most secure access privileges that approximate the privileges you selected. If you close the dialog box and choose Sharing again, the selected privileges may be different than those you selected. In Mac OS 8.0, the Sharing dialog box uses the AppleShare IP access privileges.
- Some older versions of HyperCard XCMDs that mount AppleShare volumes are incompatible with this version of the AppleShare client software.
- Microsoft Office Manager causes the AppleShare client version 3.7 to crash when you try to connect to an AppleShare file server. To correct this problem, install Office Manager Updater, available from Microsoft.
- Versions of the Novell NetWare User Authentication Modules prior to version 5.11 are incompatible with AppleShare client version 3.7 and later. Contact Novell for an update of the modules.
- Utilities that mount disk images from AppleShare file servers may have problems with the AppleShare client version 3.8.2. If you have problems, contact the developer for a new version of the utility. Apple Disk Copy version 6.3.1 or later is compatible with the new version of the AppleShare client software and is the only application for mounting disk images that Apple supports.
- Server management applications that mount AppleShare volumes may have problems with the AppleShare client version 3.8.2. Contact the developer for an update of the application.
- If there are volumes set to mount at startup and the server administrator disables the "Enable users to save password for automatic log on" checkbox in Web & File Admin, you will be unable to change the startup mounting settings for those volumes. If this happens, throw away the AppleShare Prep file in the Preferences folder (in the System Folder) and use the Chooser to reselect the server volumes you wish to mount at startup.
- To allow mounting volumes when you start up your computer using a TCP/IP connection, be sure to delete the AppleShare Prep file in the Preferences folder, and use the Chooser to reselect the volumes you wish to mount at startup. Doing this saves the TCP address of the server in the AppleShare Prep file.
- If you are having problems mounting volumes when you start up your computer using a TCP/IP connection, try setting TCP/IP to always load. If that doesn't work, try turning on virtual memory using the Memory control panel.
- If you mount a volume automatically at startup and the server software is a version prior to version 5.0, on upgrading the server to version 5.0 or later you should throw away the AppleShare Prep file and use the Chooser to reselect the server volumes you wish to mount at startup. This will prevent problems with server volumes mounting twice.
- If you are receiving "Server not responding" errors when connecting to the server using TCP over PPP, use the AppleShare Client Setup utility (available on the Apple Support Web site at www.apple.com/support) to increase the TCP Lookup timeout from 20 seconds to the time it takes the PPP link to connect plus 20 seconds.
- If the Chooser waits 2 minutes when you connect to a server using TCP, use the AppleShare Client Setup utility (available on the Apple Support Web site at www.apple.com/support/) to reduce the TCP Connect Timeout from 120 seconds to 20 seconds. Reducing the TCP Connect Timeout may make connecting to AppleShare servers over the Internet impossible.
- If you have TCP/IP set to use PPP to connect to a server and you open an alias to an AppleShare IP server (or any other server that supports AFP over TCP/IP), the AppleShare client software will try to connect using TCP/IP first before using AppleTalk. If you do not want this to happen, you can use the the AppleShare Client Setup utility (available on the Apple Support Web site at www.apple.com/support/) to disable TCP/IP support in the AppleShare client.
- If you have an alias to a server that supports AFP over TCP/IP, and the server is behind a firewall that doesn't allow pings to go through, you will not be able to connect via the alias unless you use the AppleShare Client Setup utility (available on the Apple Support Web site at www.apple.com/support/) to disable address verification via pings.
- If you have a Global Village 56k Flex Modem card and you are using PPP version 1.0.1 to connect to your Internet service provider (ISP) using TCP/IP, you need to disable the modem software's menu bar status indicators or open PPP to connect to your ISP yourself, before using the Chooser to connect to an AppleShare file server over TCP/IP.
- If the Chooser hangs after you click the OK button in the volume dialog box, try disabling the Apple Menu Options control panel.
- If you open a TCP/IP connection to a server that is behind a firewall or other device that performs network address translation, aliases to volumes on that server may not work because the IP address that the server sends to the client software may not be an address the client

can use to connect to the server.

Mac OS X Server 1.x: About the Dec21x4Ethernet Driver

This Mac OS X Server release note describes the Dec21x4Ethernet driver.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Introduction:
This driver replaces the old driver named "SwitchEthernet". The old driver SwitchEthernet works only with DEC21140 based cards. Some of the adavtages of this new driver are:

1. It supports a wide variety of DEC2114x cards, like DEC21140, DEC21143.
2. It parses the SROM information and eliminates the need to manually supply some of the information like CSR12 values in Default.table.
3. Supports the features like Auto-detection and auto-negotiation.

Cards supported:
Znyx DEC21140 based 1port, 2port, 4 port cards and D-Link DEC21143 based 1port and 4port cards.

Cards not supported:
The Adaptec's multi-port cards, which have only one SROM, donot work with this driver. We give an error message.

Known Problem:
The auto-detection doesnot work reliably for 4 port cards. It works well with single port cards. It is recommended to plug-in the wires before starting the machine.

How to use the Driver:
In order to make the driver recognize the card, make sure the Card Matching name is listed in Default.table. We currently have the strings: "Matching" = "pci1011,9 pci1186,1101 pci1186,1110"; in the Default.table to take care of Znyx DEC21140 cards and D-Link DEC21143 based cards. if you want to try any other card, you can add the appropriate name to the above list.

The driver is loaded automatically, as it is listed in /etc/startup/0500_Devices file. The old driver "SwitchEthernet" is also provided in `/private/Devices/SwitchEthernet.config`.

Mac OS X Server 1.x: About Kerberos on Mac OS X Server

This release note describes Mac OS X Server specific issues surrounding the Kerberos version 5.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Support for Kerberos v5 in Mac OS X Server

There is limited support for Kerberos version 5 in Mac OS X Server. Due to U.S. export restrictions, the Kerberos libraries are not available in the developer tookit, and Kerberos is not yet fully integrated into the system. The authentication and administration clients, however, are available: kinit, kadmin, and other utilities are built into the system. It is therefore possible to make use of kerberos-enabled software that you add into the system.

Login support using kerberos is available in the distribution. /usr/bin/login may be replaced with /usr/libexec/login.krb5, which will use kerberos to authenticate the login session and obtain the appropriate credentials for logged in users. Similar support is available for loginwindow from /System/Library/Authenticators/Kerberos.loginauthenticator. You may choose to enable its use via the "Custom Login Authenticator" option in the "Login Window" panel in Preferences.app while logged in as Administrator.

Kerberos-enabled versions of telnet and other network clients may be available to take advantage of kerberos authentication in a future release. Domestic users may get the full Kerberos distribution from M.I.T. via FTP at ftp://athena-dist.mit.edu/pub/kerberos/

Mac OS X Server 1.x: About Linux NFS Volumes

Mounting Linux NFS Volumes Issues:

If you are using Mac OS X Server as an NFS client and you mount a Linux volume as the NFS server, you may see the message "Permission denied."

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

To solve this issue:

- Log in to the Linux server and edit /etc/exports to add the "insecure" option to the filesystem you want to mount on your Mac OS X Server.

While this solution causes a small reduction in security, you don't need to repeat this step every time you add or reinstall a Mac OS X Server client.

Note: If you cannot change the Linux server, you can work around the issue by opening Terminal on your Mac OS X Server computer and using a mount command with a "-P" options flag (for example, mount -o"-P") to mount the Linux volume. However, you must do this each time you add or reinstall a Mac OS X Server as a client to the server. Because NetworkManager doesn't support the "-P" option flag, you must add the option to the NetInfo /mounts entry if you want to use NetworkManager to mount the volume.

Mac OS X Server 1.x: About NetInfoManager

This file contains release notes for the Mac OS X Server Release of the NetInfoManager application.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

New Features

The following new features have been added to the NetInfoManager application since Developer Releases:

- A new look has been provided for the properties and values editor. Multi-valued properties are now displayed as a list of values, and must be opened (with the triangle next to the property name) in order to be edited.
- There are now cut, copy, and paste menu items (and command-key equivalents) which can be used on properties and values.
- Many inconsistencies in the user interface have been cleared up.
- NetInfoManager now has a Help menu, which provides access to the network administration online help.

Known Issues

- No support for setting up a mail server. The panel presented when creating a new master netinfo server has a checkbox labeled "Maintain the network's e-mail server." This checkbox has no effect, and should be ignored. Instructions for setting up a mail server on Mac OS X Server will be available on the Apple web site sometime after the release of Mac OS X Server.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: About Networking

This article the release note regarding networking in Mac OS X Server.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Known Issues

Enabling NetInfo Access by Clients

When a Mac OS X Server computer is configured as a NetInfo server, clients cannot automatically get their network configuration information from the Mac OS X Server server. Once you have created a NetInfo server using the NetInfoManager application, there are a couple steps that you must take before client computers can access information on the server.

Note: When you configue the NetInfo server, make sure that you have the correct settings for the Hostname, Internet Address, Netmask and Router fields as appropriate for your network. After you have made all these configurations, restart the computer.

In order for a client to be part of a NetInfo network, you must do the following:

1. **Create an entry on the NetInfo server for the client machine.**
On the server, launch **/System/Administration/NetworkManager.app**. Click the "Computers" button. For each client machine you want to be part of the NetInfo network, do the following:

a. Select the appropriate parent domain in the upper portion of the NetworkManager window.
b. Click the Create Computer button located on the Computers tab.
c. Fill in the Hostname, Internet Address, and Ethernet Address fields. The format of the Ethernet Address field is six colon-separated lowercase hexadecimal values with no leading zeroes. For example, "0:5:2:ef:be:ce:" is a valid entry whereas "00:05:02:ef:be:ce" and "00:05:02:EF:BE:CE" are not. Both the Internet Address and Ethernet Address fields must not have any extra spaces anywhere.
d. Save the entry by choosing Save from the File menu.
e. When the application asks if the selected domain is the parent domain for this host, click the Yes button

2. **Statically configure the client machine's networking information.**
In order for a client to boot properly on the network, you must statically enter its network configuration. To do this, launch **/System/Library/Preferences/Network.preference** on the client machine. Set the **Connect via** pop-up menu to **Ethernet**, and TCP/IP **Configure** pop-up menu to **Manually**. Enter values for the IP address, Hostname, Subnet mask, and Router address fields (this information should be available from your System Administrator or Internet Service Provider). Once you've entered this information, click Apply. If you are not logged in as root, you will be prompted for the root password. Enter the root password and click the Authenticate button. You must now restart the client computer for the new networking settings to take effect.

AppleTalk

The Mac OS X Server AppleTalk API is expected to change in the near future. For this reason, the header files for that API have not been included in this release. Developers who are working with a preliminary version of this API should contact ADR for support until an official API is released. In addition, developers should be aware of a potentially serious problem that is still being investigated at Apple.

The problem is that use of the `SPWrite` and `SPWrtContinue` functions can result in a system hang. When this happens, you must restart the system. Although these functions are not normally used, they are typically employed in an Apple File Protocol (AFP) server using AFP on top of ASP/ATP.

We currently have no workaround for this situation. An alternative is to use AFP over TCP/IP, which is not affected by this bug. When a solution has been found, we will notify developers through the usual channels, and will post a new version of the Mac OS X Server kernel.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: About NetworkManager

This file contains release notes for the NetworkManager application. NetworkManager lets you edit information in NetInfo domains at a higher level than NetInfoManager allows. Instead of operating on the raw data in NetInfo, as NetInfoManager does, NetworkManager represents this data as hosts, users, groups, and so on.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Undocumented Features
The following features have been added to NetworkManager but are not currently documented:

Domain Browser Default Settings
When NetworkManager is opened, a user default sets the initial selection of the domain browser. This default, DefaultStartupDomain, can have the following values:

> **RootDomain**
> Causes the domain browser to display the root ("/") domain.
>
> **LocalDomain**
> Causes the domain browser to display the local (".") domain of the machine that is running NetworkManager.

You can set this default in a Terminal shell by entering the following at the command line:

```
defaults write NetworkManager DefaultStartupDomain RootDomain
```

NetworkManager remembers the last selected domain and uses that as the selection for new windows. In the future these defaults will be selectable in a preferences panel.

Known Issues

These new issues have been identified in the Mac OS X Server Release.

Issue	Nothing is ever written to /var/log/nu.log
Description	In the User and Group template panels it is possible to specify a log file. However this file is never created and no output is ever written to it.
Workaround	There is no workaround for this problem.
Issue	Difficulties exporting mutiple directories on same filesystem to same clients.
Description	Each export specifies the mount point and export flags within one local server filesystem for one or more hosts. A host may be specified only once for each local filesystem on the server and there may be only one default entry for each server filesystem that applies to all other hosts. This default entry exports the filesystem to the ``world'' and should be used only when the filesystem contains public information. Since /Local/Public and /Local/Users are both part of one filesystem they may not be separately exported to the same host(s).
Workaround	Export the entire filesystem on which the directories which one wishes to export reside, using the "Export Entire Filesystem" option.
Issue	Prompt to re-enter password on save to domain of an unmodified user.
Description	When attemting to save an unmodified user to a domain using the "File:Save To Domain..." menu item. A prompt appears asking to re-enter the users password. Entering the correct password still fails the operation.
Workaround	Enter a new password for the user in the "Password:" field. Then select "File:Save To Domain...", finally when prompted enter the new password again.
Issue	Some options are currently not supported in Mac OS X Server.
Description	Kerberos authentication does not work in the File Sharing controls. TCP Transport (In the Advanced Import Options.) does not work..
Workaround	Never select these options in the file sharing panels since they do not work.
Issue	NetworkManager cannot administer exports and imports of OpenStep networks.

Description	Due to incompatibilities in the schema for exports and imports creating or modifing exports or imports on netinfo databases with OpenStep clients attached to them with NetworkManager may cause unexpected behaviour of the OpenStep clients.
Workaround	Use the tools that came with OpenStep to administer domains with OpenStep clients. Mac OS X Server does understand the old schema. However, it does not allow for as much control as NetworkManager currently does.

Mac OS X Server 1.x: About QuickTime Streaming Server (Preview Release)

This article is the release note for the Preview Release of QuickTime Streaming included with Mac OS X Server.

This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"

QuickTime Streaming Server 1.0.2 Update is available for downloading. For more information go to:
Article 60462: "**QuickTime Streaming Server 1.0.2 Update: Read Me**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

This version of Mac OS X Server includes a special preview release of the QuickTime Streaming server. This preview allows you to explore the delivery of rich digital media over the Internet or intranets to any QuickTime-capable application.

Important: The QuickTime Streaming server preview release expires on January 31, 2000. Telephone support is not available for preview products, such as QuickTime Streaming server.

Note:

To view QuickTime streaming media, you need the latest version of the QuickTime client software. See the QuickTime Web site at **http://www.apple.com/quicktime/**.

To receive information about QuickTime Streaming server updates, join the QuickTime Streaming server public mailing list. By joining the list, you can share experiences, questions, and comments with others using the software. Apple employees may monitor these lists, but Apple does not guarantee that questions sent to this list will be answered. For more information about joining the mailing list, see the Apple mailing lists Web site at http://www.lists.apple.com/.

Known issues and solutions

- If users receive a 415 error when they attempt to view a streamed movie, be sure you save the movie you want to stream as a self-contained movie using your authoring software (for example, QuickTime MoviePlayer).
- If you have difficulties reflecting several movies to multiple clients at the same time, be sure that you set up the QuickTime application that transmits the live multicast so that each multicast source and each broadcast source has a unique port number.
- Do not use MacIP as the TCP connection method for client computers that are playing QuickTime Streaming media. To change the connection method, open the TCP control panel and choose the method you want to use from the "Connect via" pop-up menu.
- QuickTime Streaming server accepts connections on ports 554 and 7070. If your client computers are behind firewalls, users may find it easier to connect to the server by including 7070 as an explicit port number in the URL (for example, rtsp://myserver.my.com:7070/mymovie).
- QuickTime Streaming server can use only the built-in Ethernet port of your server computer. It cannot use the 4-port Ethernet card. Be sure to provide the IP address or domain name of your built-in Ethernet port for streaming.
- The version of QuickTime MoviePlayer provided on your Mac OS X Server computer does not support some new formats, so you may be unable to view some QuickTime Streaming media using this version of MoviePlayer.

Mac OS X Server 1.x: About Security With Mac OS X Server

This document describes some actions that you can taken to adjust the security of a Mac OS X Server configuration.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Network services

The Network settings panel lets you turn on these services:

- Web server
- Remote shell
- Remote login
- Remote printing
- Remote Mach IPC
- FTP server
- Telnet server
- Finger
- Mail server

Turning on any of these services may reduce the security of your system. Turn on only those service that are necessary for your particular installation.

Denying access to FTP services

If you turn on the FTP server, then you can deny access to specific users by listing their user names in /etc/ftpusers.

Denying access to LPD services

If your server computer acts as a print server, then you can restrict print services to specific client computers. To do so, edit /etc/hosts.lpd so that it lists the host names of the clients.

If /etc/hosts.lpd contains a line consisting of a single plus sign, then print services will be available to any client. If you want to restrict access to specific clients, make sure that /etc/hosts.lpd does not contain a line consisting of a single plus sign.

If print service is turned off in the Network settings panel, then /etc/hosts.lpd will be renamed as /etc/hosts.lpd.disabled.

Password shadowing

Passwords in Mac OS X Server are stored in a protected form so that the original password cannot be recovered directly. However, there remains the possibility that someone might guess a password. For this reason, even the protected passwords are hidden (or "shadowed") from unprivileged users.

When an executable without special privileges uses BSD-level APIs such as getpwent, getpwnam, and getpwuid, an asterisk ("*") is returned for the passwd field rather than the actual protected password.

In addition, user records in NetInfo are created by default with a _shadow_passwd property. If this property exists, then unprivileged executables retrieving those records from NetInfo will receive an asterisk rather than the actual protected password.

Note: This feature is actually more general. Any property in a directory that contains _shadow_propertyname will be so shadowed. The _shadow_propertyname doesn't need a value. If it has values, they are ignored.

For this protection to be effective, it is still necessary that you restrict access to your NetInfo domains to trusted hosts as described later in this section. Because even protected passwords for network accounts may still be vulnerable to sniffing as they pass across the network, it's important to control all access to your local network.

If it is necessary for an unprivileged executable to perform password-based authentication, then it's possible to do so by invoking the setuid-root executable /usr/libexec/chkpasswd, passing it the user name as an argument and the password via a pipe. A non-zero exit code indicates that the password is incorrect.

Note: Chkpasswd accepts the same options as passwd and uses getpass() for its input. It may be necessary to call setsid() in the child before executing it. This will be done automatically if it is invoked from the Yellow Box using NSTask.

Versions of NetInfo prior to that shipped with Mac OS X Server will not shadow passwords and will ignore the _shadow_passwd tag. For the most part, old and new versions of NetInfo can work together and serve both old and new clients. The one exception occurs if you perform from an older client computer an administrative operation, such as changing the password, on a user record stored on a new Mac OS X Server NetInfo server and the record contains the _shadow_passwd tag,. In this case, you may need to open the administrative application as root to perform the operation. Alternatively, you can remove the _shadow_passwd tag from the account.

NetInfo

You can limit access to a NetInfo domain by creating a top-level property listing the Internet addresses of those networks that are allowed access to the NetInfo domain. In most cases, this property is created by default when you create a domain.

You may want to change this property later. The values of this property should be the IP network addresses of networks to which you want to grant access. These addresses must have one of these forms:

```
17

17.202

17.202.15
```

Alternatively, it is possible to refer to a network by name, if that name is listed under /networks within the same domain.

If the trusted_networks property does not exist, access will be granted to anyone. Access will always be granted to the local computer on which the domain is being served.

If the property exists but has no values or no valid values, then access will be denied to all but the local computer. This should be the default for the local NetInfo domain, but this will prevent remote administration of the local domain. See the NetInfo man pages and documentation for more information.

Note: Because IP is not a secure protocol, filtering based on IP addresses may not be effective, depending on your network configuration.

Mach IPC and distributed objects

A number of facilities in Mac OS X Server use Mach IPC for communication. This includes those that make use of distributed objects, whose default transport mechanism uses Mach IPC, as well as others, such as the window server.

The nmserver has the capability to allow Mach IPC to be communicated transparently across the network. This allows for such features as the NSHost remote window serving. NSHost in particular can be turned off for security purposes using the 'Private Window Server' setting in the Expert Preferences module. However, the private window server setting does not protect the other facilities that make use of Mach IPC, which need to be protected for the same reasons and under the same circumstances as the window server.

To protect all of these facilities, nmserver has several new options.

First, you can use the Network settings panel to turn on or off the capability to act as a server for remote Mach IPC. This controls the MACHIPC setting in /etc/hostconfig, setting it to either -LOCAL- or -SECURE-. With the -SECURE- setting, the nmserver will refuse all remote lookup requests. With the -LOCAL- setting, responses to remote requests will be controlled by the file /etc/nmserver.access.

The default /etc/nmserver.access file contains entries allowing access to all of the standard Apple-supplied services for which remote access is likely to be useful, including NSHost, Yellow Apple Events, Terminal services, remote build services, WebObjects monitoring, etc. If you have an additional DO-based or Mach IPC-based service to which you want to grant remote access, add an additional line to this file consisting of the name under which the service is registered, followed by a colon, then by a comma-separated list of the IP network or host addresses to be granted access, or a plus sign to grant access to anyone. A question mark used in the service name acts as a wild card for any single character, an asterisk for any number of characters. If you want to restrict access to some of the Apple-supplied services, then edit the corresponding lines in the file. To disable a particular line, you may turn it into a comment by preceding it with a pound sign.

Alternatively, the MACHIPC setting in /etc/hostconfig may be changed to -UNRESTRICTED-. This will grant access to any service to any host. This should be done only in well-controlled network environments. Another alternative for particularly hostile network environments, is to add a flag -nevernet after the -nonet flag in the invocation of the nmserver in /etc/startup/0500_MachMessaging. This will prevent the nmserver from ever connecting to the network and any use of remote Mach IPC. However, this will interfere with some applications (including the Blue Box) and is not intended for normal use.

The IP network or host addresses used in /etc/nmserver.access may use any one of the formats given above for trusted_hosts, or a variety of other formats, including the ability to specify ranges of addresses or subnet masks. For example:

```
17.202.12.0 / 255.255.252.0

17.202.15.177 - 17.202.15.181

17.202.4 - 17.202.12 / 255.255.252.0
```

Note: Because IP is not a secure protocol, filtering based on IP addresses may not be effective, depending on your network configuration.

Mac OS X Server 1.x: About The Group Wheel

These release notes cover the use of the group "wheel", particularly with respect to the su command, and how it difference slightly on Mac OS X Server from other 4BSD systems.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Notes on group wheel and special administrative access for non-root users

The program that gives you command-line access to a root shell while you are logged in as a regular user (/usr/bin/su) behaves slightly differently on Mac OS X Server than on other 4BSD systems. The usual BSD behavior is that only users in the group wheel may use su to gain access to a super-user (root) prompt, unless the group wheel does not exist or has no users in it. On Mac OS X Server, the behavior is the same, except that when the wheel group is empty or nonexistent, nobody can su. This was done due to a difference in how we look up a list of users in a group on Mac OS X Server (which is hierarchical, not the usual flat as in /etc/master.passwd).

Users who would need to have special administrator access should be explicitly added to group wheel via Network Manager. Note that adding a user to the wheel group on your parent NetInfo server (if applicable) grants that user such access on all machines inheriting configuration from that server, while adding a user to a local wheel group grants special access only on the local machine.

The local user account that is optionally created with Setup Assistant is automatically added to the wheel group under the assumption that this user is the primary user of the machine and therefore should have such privileges. Note that the user is added to the local wheel group, not a network wheel group, and therefore only has such privileges on the local host.

The special privileges granted to users in group wheel include the ability to use the su program to gain a root prompt and the ability to edit files which are otherwise restricted, such as the web server documents and configuration in /Local/Library/WebServer. There may also be other privileges granted depending on the configuration of the machine. Beware that users with such privileges may be able to compromise a system and obtain root-level access even without the administrator (root) password. One should therefore limit such privileges to trusted users and only on appropriate hosts. The ability to log in as root via loginwindow (if one knows the password) is not affected by which users are in group wheel, nor is the ability of users with the root password to use system management tools such as NetworkManager to gain certain privileges which are only otherwise available to the root user. Restricting wheel users does not prevent this form of obtaining root privileges.

One cannot log into a machine remotely via telnet as root (unless root has no password), and therefore users who wish to obtain root access remotely must first log in as a normal user and then use su to gain root access. By restricting wheel access you can therefore reduce the probability that a compromised account will result in an intruder obtaining privileged access via the network.

Mac OS X Server 1.x: Apple Menu Release Notes

These notes are for the Mac OS X Server Apple Menu.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

You can customize the contents of your Apple Menu by selecting the Configure Menu item from the Apple Menu. If, for some reason, the Configure Menu item is not available, you can launch the AppleMenuOptions application directly from the Workspace Manager. The application is named AppleMenuOptions.app and is located in the /System/Applications folder.

Each user can configure the Apple Menu as he or she desires without affecting the Apple Menu configuration of the other users of the system.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: About Exception Handling on Mac OS X Server

This release note describes a new user default for controlling the behavior of applications in response to certain types of errors.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Application Errors

Certain types of application errors typically cause Yellow Box applications to exit abruptly. A new user default, NSExceptionHandlingMask, has been provided to control this behavior (for AppKit-based applications only) for three of the most common classes of such errors:

- uncaught NSExceptions;
- system-level exceptions (such as invalid memory accesses); and
- Objective C runtime errors (such as messages sent to freed objects).

Setting NSExceptionHandlingMask causes the application to optionally (a) print a descriptive log and a stack trace to the console when such an error occurs, or (b) handle the error in such a way as to prevent the resulting abrupt termination, or both. The mask is constructed by summing values corresponding to the types of errors to be logged or handled: 1 for logging uncaught NSExceptions, 2 for handling them; 4 for logging system-level exceptions, 8 for handling them; 16 for logging runtime errors, 32 for handling them. Thus

```
defaults write NSGlobalDomain NSExceptionHandlingMask 63
```

will cause all of these types of errors to be both logged and handled for all applications.

System-level exceptions and runtime errors are handled by converting them into NSExceptions. NSExceptions generated in this manner will contain a stack trace in their userInfo under the key "NSStackTraceKey". Uncaught NSExceptions are handled by terminating the thread in which they occur (NSExceptions in an application's main thread are caught by NSApplication's top-level handlers).

In addition to the use of the NSExceptionHandlingMask user default to control this behavior for AppKit-based applications, the same functionality can also be accessed programmatically from both application and non-application Yellow Box executables by linking against the ExceptionHandling framework and calling

```
[[NSExceptionHandler defaultExceptionHandler] setExceptionHandlingMask:aMask]
```

See the ExceptionHandling.framework header files for more details on the NSExceptionHandler API.

Debugging Aids

For debugging purposes, it is also possible to use the same mechanism to report on NSExceptions that would otherwise be caught. The additional values that may be added to NSExceptionHandlingMask for this purpose are 64 for logging exceptions that would be caught by the top-level exception handlers in NSApplication, 128 for handling them, 256 for logging exceptions that would be caught at lower levels, and 512 for handling them. In these cases, handling an exception means nothing more than adding a stack trace to its userInfo under the key "NSStackTraceKey". Note that caught exceptions should be logged or handled only for debugging, not under normal circumstances, because doing so may generate large amounts of output, or alter the normal behavior of applications.

For further debugging purposes, it is possible to change the handling behavior for any condition handled by NSExceptionHandler so that the application will instead be halted to wait for a debugger to be attached. This is controlled by the NSExceptionHangingMask user default, constructed by summing values corresponding to the conditions under which the application should hang: 1 for uncaught NSExceptions, 2 for system-level exceptions, 4 for runtime errors, 8 for top-level caught NSExceptions, and 16 for other caught NSExceptions.

In addition, a tool called atos has been provided to convert numeric stack traces into symbolic form. See the atos(1) man page for details.

Mac OS X Server 1.x: Floppy Disk Driver Release Notes

Release notes for the floppy disk driver in Mac OS X Server.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Known Issues

The Floppy Driver supports MFM formats like 1.44MB, 720 MB floppies. At present we do not support Formatting and writing of GCR Formats like 400K and 800K. So we mark GCR floppies as Write Protected.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: About Mac OS Format Volumes

Release notes about Mac OS Format volumes for Mac OS X Server.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Filesystem performance

Filesystem performance on any Mac OS format disks (Standard or Extended) using Mac OS X Server will be dramatically affected by the allocation block size on a given disk or partition. The system is designed to accelerate input and output (I/O) only to files on volumes whose allocation block sizes are an even multiple of 4K; I/O to files on volumes with smaller or larger allocation blocks will be slower.

Optimal Mac OS Standard format volume size ranges are 32 MB in size ending at multiples of 256 MB:

- 224 - 256 MB
- 480 - 512 MB
- 736 - 768 MB
- 992 - 1,024 MB
- 1,248 - 1,280 MB
- 1,504 - 1,536 MB
- 1,760 - 1,792 MB
- 2,016 - 2,048 MB

For the best performance on a Mac OS Standard format disk, you should partition the disk using these size ranges.

Allocation block sizes on Mac OS Extended format volumes are determined using a different algorithm and the allocation block size on these volumes will never be larger than 4 KB. Volumes under 2 GB will be created with increasingly larger allocation block sizes up to 4 KB and any volume or partition 2 GB or larger in size will be created with an allocation block size of 4 KB. Mac OS Extended disks or partitions should therefore be at least 2 GB in size for optimal performance.

An easy way to verify the allocation block size on any disk is to use Get Info in the Finder to check the size of a small file. Alias files should take exactly one allocation block on disk. The size on disk should be 4 KB, 8 KB, 12 KB, 16 KB, or some other even multiple of 4 KB.

Using Yellow Box or BSD applications

Yellow Box and BSD applications, such as TextEdit, Emacs, and vi, were not written to make use of resource forks or certain other information associated with files on a Mac OS Standard or Mac OS Extended format disk. As a result, using these applications to open and save files created on Mac OS, Mac OS Compatibility on the Mac OS X Server, or AppleShare can lead to lossing the resource fork or other information, such as the Finder information which contains the type and creator of the file.

Differences between Mac OS Standard and Mac OS Extended formats affecting MacOS X Server

In addition to the usual advantages of the Mac OS Extended format, there are several features in the Mac OS X Extended format that are specific to Mac OS X Server operation. Because of these feature differences, you should always format Mac OS disks for Mac OS X Server using the Mac OS Extended format rather than Mac OS Standard format.

The main differences follow:

- Support for file and directory based permissions. Mac OS X server supports file and directory permissions the same way that BSD systems do. The Mac OS Standard format cannot store this information. All files and directories on Mac OS Standard format volumes have a universal permission set to allow read access to all users and both read and write access to root users and the Blue Box and cannot be changed. Attempting to change the owner, group, or permissions of a file on a Mac OS Standard format volume will not change any values, although no error message reports the failure. Mac OS Extended format volumes can store permission and other security information about files. If permissions have never been set for a file or directory on a Mac OS Extended format volume, the universal permission set is used. Users may, however, change the permissions on a file or directory on a Mac OS Extended format volume and those user set values will be stored and used.
- Support for BSD file types. The Mac OS Standard format cannot store BSD file type information. This is especially noticeable with symbolic link files which are not supported on Mac OS Standard format volumes. The Mac OS Extended format can store this information, so link files are supported.
- Support for AppleShare. You cannot share Mac OS Standard format volumes using Apple file services on Mac OS X Server, unless those volumes are on CD-ROM media.

Mac OS X Server 1.x: About Installation Applications

These notes are for the Mac OS X Server installation process, including the installation tools used to boot the system from a CD, install a base system, and install packages and updates to the system.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Mac OS Tools

The Mac OS X Server CD includes an installer application, as well as System Disk Control Panel and Extension. System Disk, which allows you to switch between booting into Mac OS and Mac OS X Server, replaces Multibooter of previous releases. For information on these tools, consult the Read Me files on the CD.

Installing Multiple Languages

The Mac OS X Server includes French, German, and Japanese localization packages. These add localized resources to certain core applications, such as the Workspace Manager, Installer, NetworkManager, and TextEdit. More complete localizations will be part of Japanese, French, and German versions of Mac OS X Server, which will be released this Spring. Note that the localization these application display depends on the order of languages the user has chosen in the Localization User Preference.

These packages can be selected as optional languages at installation time, and are available on the Mac OS X Server CD in System/Installation/Packages/*language*Essentials.pkg if you want to install them at a later time. Their contents can also be removed, like other packages, by opening the receipt in /Local/Library/Receipts.

Choosing optional languages at install time also determines which localized MacOS.app startup disk images are installed. This is not the case if you install a language after the OS installation process. If you want to install a new localized disk image, reinstall the package System/Installation/Packages/BlueBox.pkg on the Mac OS X Server CD, and select that language.

If you've installed the Mac OS X Server SDK, and are interested in developing localized applications, consult the Localization Read Me for more information.

Mac OS X Server Installer application

The Installer application (located in /System/Administration/Installer.app) is the tool used by administrators to install and remove software in Mac OS X Server.For information on how to create packages, see the Read Me Creating and Installing Packages.

Known Issues

* During installation of multi-package bundles, such as the Mac OS X Server SDK, the Installer may show alert panels referring to an unnamed log file. This file is located in:

/tmp/*filename***.installerLog**

where *filename* is the name of the multi-package bundle being installed (without the **.mpkg** extension).

* Version information for multiple package bundles isn't displayed anywhere in the Installer UI.

* The Installer fails to indicate when individual packages in a multiple package bundle have already been installed. Also, there is no facility for deleting installed multiple package bundles: you have to delete the individual installed packages.

* Installer now uses the pax tool to create and read packages. OpenStep packages created with tools that predate the Rhapsody Developer Release do not work with the Installer application included with Mac OS X Server. Packages created in Developer Release 2, which used the gnutar tool, can be installed by Installer, although the application fails to give feedback on each individual file as it is installed.

Mac OS X Server 1.x: About Japanese on Mac OS X Server

Mac OS X Server lets you edit, display, and print Japanese text. Most of the applications included with this release are capable of handling the complex language using the internationalization feature of Mac OS X Server. In addition, applications developed for Mac OS X Server are automatically Japanese-ready, unless they have language dependent needs or features.

This document describes features and issues specific to Japanese.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Contents

- Configuring the system default character encoding
- New features
- Known issues

Configuring the system default character encoding

Mac OS X Server uses the Unicode character set. Unicode lets applications handle thousands of characters from multiple languages, including Japanese, simultanously.

Note: Mac OS X Server provides the transmission-friendly format of Unicode (UTF8) as the default system encoding.

To provide backward compatibility and inter-operability on other platforms, Mac OS X Server allows users to configure the system's default character encoding. The system character encoding setting governs how Mac OS X Server treats "plain text" files, filename character encoding, and application-specific default character encoding configurations such as MailViewer's default character encoding for plain text messages.

Because the default setting is Mac OS Roman, US and Western European users typically do not neeed to change the encoding setting. On the other hand, Japanese users should set their system default encoding to Japanese EUC. Setup Assistant automatically sets the configuration to Japanese EUC if the user select Japanese as the system language.

When you switch to a Japanese setting, the following components change their default character encoding handling:

- Mac OS X Server reads and writes plain text files in Japanese EUC character encoding if they are not already in Unicode.
- The default value for the Java "file.encodng" property is set to EUCJIS.
- The default character encoding for plain text messages sent or received by MailViewer is set to ISO 2022 JP.

You can change the default character encoding configuration by editing the text file at /System/Library/Frameworks/Foundation.framework/Resources/CStringEncoding. The default character encoding is Japanese EUC if the file contains the character "3" at the beginning, and Mac OS Roman if the file contains "30" or the file does not exist.

New features

The following new features have been added for Japanese text handling.

Automatic default input server launch at login

Workspace Manager now opens and initializes the user's default input server when the user logs in to the server. This reduces the delay before opening the input server the first time. The Canna Japanese Input Method is initialized if the system language is set to Japanese.

Default system character encoding configuration at installation

Setup Assistant now configures the default system character encoding to Japanese EUC if the system language is set to Japanese.

Known issues

Apple JIS keyboard support

On Apple JIS keyboards, typing the Yen (¥) key generates a backslash (\\) character. To enter the Yen symbol, type Option+Y.

Font settings in Japanese environment

For the best look and performance, you should change the font settings to use Japanese fonts using the Appearance control panel.

You cannot select fixed variants of the Heisei fonts for the Fixed Pitch Font setting.

Mac OS compatibility

For the Japanese Mac OS, the startup disk image requires at least 150 MB of disk space, not 100 MB as mentioned in About Mac OS Compatibility.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: About Apple Multiscan 720 Display

Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

This article contains the Mac OS X Server release notes for the Apple Multiscan 720 Display.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.

Known Issues

Issue	The Apple Multiscan 720 Display may seem to only support 640 x 480 on some graphics cards, usually older cards.
Description	The Multiscan 720 defaults to require a DDC-capable graphics card to recognize the display and determine its capabilities. Some third party graphics cards and older Apple machines (pre-G3 series) may not support DDC and will allow only 640 x 480, unless the workaround below is used.
Workaround	The display can be configured with its front panel and onscreen display to disable DDC. When this is done, additional modes should be available on all supported graphics cards. A reboot is required after changing the monitors configuration.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: About Printing

This article contains the Mac OS X Server release notes about printing.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Security Issues

All Mac OS X Server machines are set up to disallow computers on the network to print to printers configured for that machine. If you wish to share a printer you will have to edit (as root) the file /etc/hosts.lpd to select which computers you wish to permit printing privileges - you must then reboot the machine to make the changes take effect. Please see the man page for hosts.equiv for information on the format of this file.

PrintManager

This application allows NetInfo printer entries to be created and exported to other domains. You may view, delete or get information about jobs in a printer queue.

Known problems and workarounds:

1. Viewing Print Queue only works 1 time.
   - Workaround: Quit and re-launch PrintManager.
2. Cannot create/export remote printer entry if the domain need authentication.
   - Workaround: Use NetInfo.app to create the printer entry.
3. Cannot select any printer specific options from a PPD file.
   - Workaround: Remove the execute bit from the PPD file located in /System/Library/Printers/PPDs/Apple/Resources/
4. First local printer entry created does not update the Tabs correctly.
   - Workaround: Click on the tabs again.

Backward Compatibility

Because of the directory restructuring, printing to a Rhapsody Developer Release 1, NextStep, or OPENSTEP network printer from a Mac OS X Server computer does not work. This is because the Spooling Directory specified in the NetInfo entry for the printer does not exist on the Mac OS X Server system. There are two workarounds:

1. Rename all the **/printers/**[*PrinterName*] "sd" property keys to be "_sd". We have experienced no problems with legacy systems being able to print (if no spooling directory is specified, a default one is used).
2. Create the spooling directory on the Mac OS X Server system. This workaround is less desirable as it will have to be repeated for all new systems.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: About Disk First Aid

This article contains the Mac OS X Server release notes on Disk First Aid.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Differences in Disk First Aid versions

The version of Disk First Aid provided with Mac OS X Server works the same as version of Disk First Aid provided with Mac OS 8.1. The version of Disk First Aid provided with Mac OS 8.5 can detect and repair some disk problems that the version of Disk First Aid with Mac OS X Server cannot detect or repair.

If Disk First Aid on a Mac OS X Server computer reports a problem but says it cannot fix the problem or if you experience disk problems after Disk First Aid reports repairing your volume, you can try using the version of Disk First Aid with Mac OS 8.5. To do this, start up the computer wiht Mac OS 8.5 then open Disk First Aid. Alternatively, you can mount the volume in the Blue Box using exclusive mode, then open Disk First Aid on that volume in the Blue Box.

Using Disk First Aid on mounted volumes

If you use Disk First Aid to verify or repair a Mac OS Standard or Mac OS Extended volume with an open file or application on it, you will see a message that Disk First Aid is unable to unmount the volume.

- You may see this message in these cases:
- You have shared the volume as an Apple file services volume.
- You are using the volume with NetBoot services.
- You chose Mac OS from the Apple menu.
- In Terminal, you changed the directory to a folder on the volume.

To use Disk First Aid to verify or repair the volume, close any open files and quit any open applications. If you are using Terminal, quit Terminal.

If you have turned on Apple file services or NetBoot services, you may need to stop the AppleFileServer processes. To do this:

1. Open the Apple menu and choose Server Administration, then choose ProcessViewer. If necessary, choose All Processes from the Show pop-up menu.
2. Find the two AppleFileServer processes and select both.
3. Open the File menu and choose Quit Process, then click the Quit button to stop each process.

Note: The server may create a new AppleFileServer process after you complete these steps. Before continuing you should check if there is a new process and, if so, stop the process.

You should also make sure any NetBoot clients are shutdown before stopping the Apple File Server process. If this is not done, the workstations will freeze and any work users have not saved will be lost.

You should now be able to use Disk First Aid to verify or repair the volume.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: About the Find Application

This file contains release notes for the Mac OS X Server Release of the Find application. Items specific to the current (Mac OS X Server) release are included.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Find

Find for Mac OS X Server integrates the functionality of Find By Content and Find File within a single tabbed window. Find can be accessed from the Apple menu. Find opens with the Find File tab frontmost by default.

Find File

The File File tab allows an non-indexed search of files on the System. Clicking the More Choices button at the bottom left of the tab can refine the search. This increases the size of the window and adds new search criteria. Clicking on the Fewer Choices button removes a field and reduces the window size to fit. The Fewer Choices button is disabled when only one option is available. The More Choices button is dimmed when eight options (the maximum) are visible.

The volume popup lists a number of useful directory paths such as Home, Root and a series of paths that are chosen from a submenu.Note that choosing the menu item (i.e. applications) will not work. The user must choose the specific submenu item.

The Browse... button brings up the open dialog and allows the user to add favored directories to the volume popup menu. Added directories are appended to the volume popup menu and last a session only.

A maximum of eight search criteria are possible. Each one has one or more modifiers, accessed in the middle popup. The default modifier is <is>.

Drag and Drop to Search Fields

Dragging a file to the Find File dialog will update all the visible fields for that file, including the permission fields and the date modified field.

Searching

When the user presses the Find Button, the search commences and the Find button changes to a Stop button. All items in the window are disabled (except for the feedback field and Stop button). A spinning arrow in the top right of the window indicates activity. The items found field in the bottom center of the window lists the number of items found.

Pressing the stop button will abort the search and display the results collated up to the abort.

If no items are found an alert is shown.

Threading Finds

More than one find can be run simultaneously. By choosing Reset Find from the file menu or Cmd-R the user can enable all fields while a search is still running. He can then modify his search criteria and launch a simultaneous find by pressing the Find button. This again will disable all fields. By again choosing Reset Find the user can continue to modify and launch new finds. Ten finds can be threaded.

Note that the item found field will display results from all finds and appear non-sequential.

Choosing the Stop button in this case will bring up the Process Dialog.

Process Dialog

The Process dialog can be launched from the Recent Processes menu item in the Window menu. Or more likely it is shown if a user tries to stop a multi threaded find.

The Processes dialog lists all threads running at that time in a table. The user can abort any search by clicking on it in the table. This enables the Stop button and displays more information for that find in the status fields. Pressing the Stop button aborts the search for the listed find and displays the result window.

Results Window

The result window is the window where the results of the search are displayed to the user. The window is divided in two distinct parts separated by a resizable splitview. The top of the window contains a table that lists the results in columns. The columns order the results by Document, Size, Last Modified, Type, and Owner. The results are originally shown sorted by name. Clicking on the column will sort by that column. Columns can be reordered and resized.

Clicking on a row of this column will display the icon path of the file in the bottom view. Files can be dragged from the Icon path view to the desktop or to another volume or folder. Files can also be dragged from the workspace to the icon path view or from different result windows. The modifier keys determine the type of drag, as in the workspace. The items found field in the bottom left hand side displays the number of items found for this search.

Find allows multiple Results windows to be open at one time. The Results window is resizable.

Saving Search criteria

A search is saved from the Favorites menu. The Save As Favorite menu item presents a dialog allowing the user to name the saved criteria. It is saved to ~user/Library/FindPreferences. The favorites menu only saves search criteria and NOT results. Each favorite is appended to the menu. Choosing a favorite menu item will reinstate the search fields (enlarging or reducing the window as necessary). The user can launch the find as usual by pressing the Find button.

Editing Favorites

Choosing Edit Favorites from the Favorites menu will launch the Edit Favorites dialog. The user can rename or remove a find from the menu. (He cannot in this release change the internal find predicates i.e. the rightmost column of the table). Choosing a favorite and pressing remove removes it from the table , menu and disk.

Find by Content

The Find by Content uses Apple Information Access Toolkit (AIAT) to create indexes of the contents of folders, which you can then search for specific contents. Only folders which have been indexed can be searched in this way.

- If you have only installed User CD, you will have an empty "Search on" popup menu. You need to click the "Indexing" button to index the folder that you want to search on. After the folder is indexed, the folder will be automatically added to the "Search on" popup menu. Then, you can enter the search words, and click the "Find" button to start the searching.
- If you have installed Developer CD, you will have the Sytem Documentation pre-indexed for you. The "Search on" popup menu has "System Documentation" pre-selected. You can enter the search words, and click the "Find" button to start the searching. If you want to search on other folders, please indexing them first, then you can search for specific contents on those folders.
- The Find by content doesn't index the files with following extensions: index, idx, o, a, gif, pdf, eps, tiff, app, fbc, x, gz, gzip, zip, tar, dylib, nib, plist, accessor, ps, afm, snd, bom, or img. And, it doesn't index the folders with app, framework, font, bundle, or palette extensions.
- There are three files in the English resources of the Find application which are used by the Find by Content to do the indexing and searching. They are abbreviations.fbc, Stopwords.fbc, and Substitutions.fbc. You can use a text editor to modify them for other languages.
- There are some menu or menu items don't apply to the Find by Content : Reset Find, Recent Processes, and Favorites.

Indexing Dialog

If you want to create the index for a folder, you can click "Choose A Folder To Index" button to select the folder . Then, you can click the "Begin Indexing" to start the indexing. If the folder has a lot of text files, it will take a while to index the folder. During the indexing, you still can search on other folders.

After the indexing is completed, the folder name is added to the "Folders which have been indexed" table, and the folder name is automatically added to the "Seach on" popup menu of the main window. Then , you can switch back to the main window, enter the search terms, and click the "Find" button to start the searching.

If you want to update the index or delete the index, you can click the entry on the "Folders which have been indexed" table to select the folder. Then, you can click the "Begin Indexing" to start the indexing. Or, you can click the "Delete Index" to delete the index.

Results Window

The result window is the window where the results of the search are displayed to the user.

The window is divided in two distinct parts separated by a resizable splitview.

If no items are found an empty result window is shown.

TA44227_Mac_OS_X_Server_x_About_the_Find_Application.pdf

The top of the window contains a table that lists the results in columns. The columns order the results by Score, Document, Size, Last Modified, Type, Owner, hit tersms, and Path.The results are shown sorted by score always. Clicking on the column will not sort by that column. Columns can be reordered and resized.

Clicking on a row of this column will display the summary of the file in the bottom view.

Mac OS X Server 1.x: Mac OS Compatibility (MacOS.app) v2.2 Release Notes

This document describes the Mac OS Compatibility environment shipped with Mac OS X Server 1.1. This environment is implemented by the MacOS.app application, sometimes referred to as the "Blue Box".

Note: This document was installed by Mac OS X Server in /System/Documentation/Read Me For a list of other release notes see article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Overview

MacOS.app, sometimes referred to as the "Blue Box", is a high-performance, high compatibility environment for running Mac OS software within the Mac OS X Server operating system.

High compatibility is achieved by running Mac OS essentially unchanged in a virtual environment, which appears to be a new Macintosh hardware model. Because of this, the vast majority of Mac OS applications, utilities, extensions and software drivers just work. Software that directly accesses hardware, uses undocumented internal APIs of the Mac OS, or relies on Mac OS managers not yet supported by this release of MacOS.app is not expected to work.

The Mac OS managers not currently supported by this release are those generally associated with hardware not yet fully supported by Mac OS X Server. Such missing functionality is explicitly listed in this document and will likely be provided in subsequent releases of MacOS.app.

This release of MacOS.app comes with Mac OS 8.5.1 and will support future versions of Mac OS that have not shipped as of this writing. Previous versions of Mac OS are not supported, and MacOS.app will not allow them to run.

MacOS.app allows you to use your current Mac OS applications to "live" on Mac OS X Server, to explore its new capabilities while preserving your current Mac OS environment.

You are encouraged to read these release notes before running MacOS.app. If you just can't resist, at least read the following "Quick Start" section.

Quick Start

To start MacOS.app, choose Mac OS in the Mac OS X Server Apple menu or double-click on "/System/Applications/MacOS.app" in the Workspace File Manager. You may also want to drag an alias onto the Workspace for quicker access to MacOS.app. It is best not to launch MacOS.app from a Terminal window, since it will not result in a clean MacOS.app shutdown when logging out from the Mac OS X Server's Workspace.

The first time you launch MacOS.app, a private Mac OS 8.5.1 startup disk image (called StartupDisk.img) will be created. The language of the image will be selected based on the Localization settings from the Preferences application and the MacOS.app languages that have been installed. The selected image will be copied and uncompressed into /Local/Library/MacOS/Users/. This process will take a little time and is accompanied by a dialog box with a progress bar. At the end of creating the startup disk image, a virtual PRAM file called "PRAM" will also be created in the same directory.

Choosing Shut Down from the Mac OS Finder's Special menu will quit MacOS.app. Similarly, choosing Restart will quit and re-launch MacOS.app. You may also use the Power key, which will bring up the standard Mac OS "Shut Down / Restart" dialog box.

To switch between the Mac OS and Mac OS X Server environments, use the Application menu at the far right of the menu bar. In both MacOS.app and Mac OS X Server, this menu has been extended to list all applications running in both environments, grouped by environment. If you choose an application that is running in the other environment, you will be switched to that environment and the selected application will be

activated.

There is a special item in the application menu of each environment that will switch you to the other environment and bring you back to the last application you were using in that environment. That item is called "Mac OS X Server" in the Mac OS environment and "MacOS" in the Mac OS X Server environment.

The following special keys combinations are available when you are in the Mac OS environment, and supersede any Mac OS use of these key combinations:

Command-Return is a shortcut for choosing "Mac OS X Server" from the application menu. Since this may interfere with some applications that use this combination of keys, you may disable it, as discussed under "User Input" in the "Bugs and Compatibility Issues" section.

Command-Shift-Q will force-quit MacOS.app. This would be equivalent to pulling the power plug out of the wall on native Mac OS and should only be used when Mac OS is hung.

All other Mac OS special keys (e.g., Command-Power for NMI - to enter MacsBug) function as expected.

Before installing software, read the section "Use of Disk Image Files", under "Working with Disk Image Files".

System Requirements

The minimum recommended RAM for running Mac OS X Server with MacOS.app is 64 MB.

Each user running MacOS.app on this machine will require a minimum of 175 MB of disk space for the Mac OS 8.5.1 startup disk image. The Japanese localized startup disk image requires approximately 200 MB of disk space.

Installation

MacOS.app is installed as part of the standard Mac OS X Server installation. Earlier versions of MacOS.app are not compatible with Mac OS X Server.

The installation consists of the following installed items:

```
/System/Documentation/ReadMe/MacOS.html
```

This release note document.

```
/System/Applications/MacOS.app
```

The application directory contains the executable file (MacOS), supporting resources and compressed localized Mac OS disk images. The particular localized disk images installed (of English, French, German and Japanese) will depend on your language selection(s) when you install Mac OS X.

```
/usr/bin/createimage
```

A command-line utility to create new disk image files (discussed under "Working with Disk Image Files").

Features

System Software

MacOS.app currently supports Mac OS 8.5.1. The supplied StartupDisk.img files contain complete default installations of Mac OS 8.5.1 except for Apple Remote Access and Text-to-Speech. These were omitted to save space and because they rely on features not yet supported by MacOS.app.

Do not attempt to install previous versions of Mac OS. Future versions of Mac OS are likely to be directly installable by running their installer in MacOS.app.

Virtual Memory

MacOS.app uses a new method for virtual memory, taking advantage of Mac OS X Server's VM system. This method, called "Sparse Virtual Memory", allows application heaps to be protected from each other with "guard" pages of unmapped memory. In addition, it allows a large number of applications to be launched, using disk space for memory as it is needed. The total virtual application memory available is 1024 MB.

MacOS.app always runs on top of Mac OS X Server's Virtual Memory, but Mac OS VM will appear to be off to applications.

Temporary Memory

In native Mac OS, an application's memory heap comes out of the same memory area as temporary memory. Since some applications allocate large fractions of available temporary memory, MacOS.app does not offer the entire unused portion of its 1024 MB sparse virtual address space as temporary memory. Instead, the temporary memory heap is created at startup time, with the size determined by the machine's available physical memory, with a minimum size of about 16 MB. Some applications may require a larger amount of temporary memory in order to run properly, and you can allocate additional temporary memory by setting SysZoneMemorySize to the desired size. For example "defaults write MacOS SysZoneMemorySize 0x10000000" will set the temporary memory size to approximately 256 MB. You may notice this difference in the Finder's "About This Computer" dialog box. In native Mac OS, the first bar (labeled "Mac OS") shows the amount of memory allocated to Mac OS and is usually almost fully in use. In MacOS.app, this bar includes the memory allocated to Mac OS plus the temporary memory allocation. On machines with a large amount of physical memory, this bar will be significantly larger.

File Systems

Throughout this document, "HFS(+)" is used as an abbreviation for "HFS or HFS+". HFS is also known as "Mac OS Standard Format" and HFS+ as "Mac OS Extended Format".

MacOS.app supports file systems on nearly all kinds of disk devices that are supported under the native Mac OS. These include, but are not limited to floppies, CD-ROMs, hard drives, and disk image files stored in the Mac OS X Server file system (UFS). Both SCSI and ATA/IDE (including ATAPI) drives are supported.

Disks can be accessed in one of three modes: Shared, Exclusive, or SCSI. Not all disk modes are available for all disks. The default access mode is Shared mode, except for disk images (which are always accessed in Exclusive mode). In order of highest-to-lowest interoperability with Mac OS X Server applications, the modes are Shared, Exclusive, and SCSI. Conversely, the modes in order of highest-to-lowest compatibility with Mac OS applications are: SCSI, Exclusive, and Shared.

Thus, there is a fundamental tradeoff involved with choosing which mode to use to access a disk. Shared mode was chosen as the default access mode because it provides a high enough level of compatibility to support typical productivity applications, while at the same time permitting access to the same disk via Mac OS X Server applications.

For more information, see the sections entitled "Disk Access Modes" and "Disk Drive Support".

Copy and Paste Between Mac OS and Mac OS X Server

MacOS.app currently supports basic Copy and Paste between Mac OS and Mac OS X Server applications.

Text can be copied (without style information) back and forth between the two kinds of applications. This includes some support for two-byte characters. See the "Bugs and Compatibility Issues" section for more details.

Pictures ('PICT') can be copied from Mac OS to Mac OS X Server applications, but are converted to RTF, which cannot be copied back to Mac OS. Many more data types are expected to be supported in future releases of MacOS.app.

Networking

MacOS.app supports Open Transport AppleTalk and TCP/IP networking using built-in Ethernet and any PCI Ethernet devices supported by Mac OS X Server. LocalTalk (AppleTalk over serial ports) is not supported. As with native Mac OS, AppleTalk networking is active by default if connected to a network.

AppleShare Client as well as Personal File Sharing, AppleShare Server and AppleShare IP Server are fully supported by MacOS.app. Personal Web Sharing is also supported.

Since Mac OS uses a different networking model than Mac OS X Server (Open Transport vs. Sockets), you must use a separate IP address for MacOS.app TCP/IP from that used by Mac OS X Server. This is best accomplished by using a static IP address in the TCP/IP control panel (or

by using MacIP - IP over AppleTalk). In previous versions of MacOS.app, when the same IP address was used for Mac OS X Server and MacOS.app, Open Transport reported an error message indicating the reason TCP/IP networking is not available. If the same IP address is used in the present versions of Mac OS X Server and MacOS.app, Open Transport TCP/IP will silently be disabled.

PCI Native Driver Model

MacOS.app partially supports the PCI native driver model. This means that the name registry, DriverServicesLib, and associated libraries are present. However, the Mac OS device tree is currently empty, so no 'ndrv' drivers are loaded.

Video

Unlike Mac OS X Server, MacOS.app can change color depth on the fly and supports multiple monitors in color depths of 8, 16, and 24-bit (256, "thousands" or "millions" of Colors or Grays). However, if Mac OS X Server is in grayscale mode, then MacOS.app will not allow depth changes.

Because of limitations in Mac OS X Server, MacOS.app cannot change resolution (size and scan rate). The resolution must be changed in Mac OS X Server's Preferences application and the changes take effect after logging out of Mac OS X Server.

MacOS.app supports multiple monitors. However, you may set it up to use only one monitor on a multiple-monitor system. MacOS.app assigns the number 0 to the main monitor (the one with the menu bar). Additional monitors are assigned the numbers 1, 2, etc. Setting the Mac OS X Server user preference "MonitorSelect" for MacOS.app to a value that indicates that monitor's assigned number will cause MacOS.app to only use that monitor for displaying video.

For example, from a Mac OS X Server Terminal window:

```
"defaults write MacOS MonitorSelect 0"
```

means only use the main monitor and

```
"defaults write MacOS MonitorSelect 1"
```

means only use the second monitor.

AppleEvents and AppleScript

AppleEvents and AppleScript are supported as usual within MacOS.app and from MacOS.app to scriptable Mac OS X Server applications.

For Mac OS X Server applications to be scriptable, they must use the Scripting Framework. Developer documentation on the use of this framework can be found in /System/Documentation/Developer/YellowBox/ReleaseNotes/

The Script Editor in MacOS.app can target applications that are running in the Mac OS X Server environment. On the local machine, targeting these applications is done the same way that targeting Mac OS applications is done.

For example, if you have a Mac OS X Server application named Sketch, you would target the application with standard AppleScript syntax:

```
tell application "Sketch"
...
end tell
```

If you are targeting Mac OS X Server applications on other machines, the syntax is slightly different and uses a semicolon between the application name and the host name:

```
tell application "Sketch;hostname"
...
end tell
```

The normal Mac OS syntax to target remote Mac OS X Server applications:

```
tell application "Finder" of machine "machine name" of zone "zone name"

...

end tell
```

is not supported in this release.

The MacOS.app Script Editor cannot get the dictionary information for a Mac OS X Server application in Mac OS X Server 1.1. This functionality will be added in a later release.

By default, Scripting between two machines is turned off for security purposes (similar to Mac OS Program Linking which is turned off as the default). The following information will help you turn on remote AppleEvents and remote AppleScripting.

The remote scripting default is called NSAllowRemoteAppleEvents.

It can be set from a Terminal window like this:

```
defaults write NSGlobalDomain NSAllowRemoteAppleEvents YES
```

It could also be turned on only for certain applications as follows:

```
defaults write Sketch NSAllowRemoteAppleEvents YES

defaults write TextEdit NSAllowRemoteAppleEvents YES
```

An API for using AppleEvents outside of AppleScript in Mac OS X Server applications has not been provided in this release.

Sound Output

Sound output is fully supported by MacOS.app, although breakup may occur during times of heavy CPU usage or memory paging. Occasionally, this may result in sound going silent altogether until the application using sound quits or MacOS.app is restarted. Playing sound in Mac OS X Server and MacOS.app simultaneously will have unpredictable results.

SCSI Manager

The Mac OS SCSI manager is partially supported in this release. It can be used via SCSI Mode for disks, as discussed in the section "Disk Access Modes", and to access non-disk devices (such as scanners and tape drives) which are not in use by Mac OS X Server.

Both the original SCSI Manager and SCSI Manager 4.3 are supported with the following limitations:

Original SCSI Manager:

- SCSIReset will not reset the SCSI bus.
- The values returned from SCSIStat provide only an approximate indication of what is going on during a transaction. Code that relies on SCSIStat to control an operation may fail.

SCSI Manager 4.3:

- MacOS.app does not support Mac OS drivers for third-party SCSI cards. Mac OS X Server DriverKit drivers are required to use these cards.
- The SCSIBusInquiry function does not return complete information about each SCSI bus.
- The SCSIResetBus function will not reset the SCSI bus.
- Command queuing functions, such as scsiQEnable, scsiSIMQHead, scsiSIMQFreeze, scsiSIMQNoFreeze, scsiSIMQFrozen and SCSIReleaseQ are not implemented.
- All SCSI transfers use DMA. Handshaking information is ignored. The scsiSelectTimeout parameter is ignored.
- SCSIAbortCommand and SCSITerminateIO are not implemented.
- The SCSI implementation will attempt to negotiate synchronous data transfer and device disconnect by default.
- scsiNoParityCheck, scsiDisableSelectWAtn, scsiSavePtrOnDisconnect, scsiDisableWide, scsiInitiateWide, and scsiRenegotiateSense, scsiNoBucketIn, and scsiNoBucketOut are not supported.
- If an application traverses the SCSI chain, devices that are already reserved or in use (e.g., by Mac OS X Server) will not be found. In order to have an application recognize a device via the SCSI manager, you must explicitly set that device to SCSI mode as described below.

Disk Access Modes

The sections below describe the tradeoffs among the three access modes: Shared, Exclusive, and SCSI. If you are just running Mac OS productivity applications, you should not need to switch the access mode for any of your disks or partitions. However, in case you need to run disk utilities - such as Disk First Aid, Disk Copy, or Drive Setup - you may need to (temporarily) switch the access mode of one or more of your disks or partitions. The "Blue Volume Mount Options" control panel is provided to allow you to set these access modes for individual disks and disk partitions. It is described below, after the explanations of the three access modes.

You can determine in which mode a volume is being accessed by selecting it in the Finder and invoking the "Get Info" command from the "File" menu. The dialog that appears includes a "Where" string that describes the mode in which the underlying disk is currently being accessed, along with an indication of the physical disk to which it corresponds. Disks accessed in Shared mode will have "Shared" in this string. Similarly, disks accessed in Exclusive mode will have "Exclusive" in this string. Disk image files (which are always accessed in Exclusive mode) will list the pathname of the disk image file. Disks accessed in SCSI mode will have a string identical to the one they would display if running native Mac OS; typically this string gives the SCSI Bus number and SCSI device ID of the drive.

For disks accessed in Shared or Exclusive mode, the SCSI bus and ID (or ATA/IDE ID) are not given; instead, they are identified in the "Where" string by their Mac OS X Server device name. In order to understand how Mac OS X Server names disk devices, you will need to consult the documentation for Mac OS X Server. Briefly, SCSI (and ATAPI) disks have names like "sd0", "sd1", etc. ATA/IDE drives have names like "hd0"; and floppy disks have names like "fd0". Disk devices may also have more than one HFS(+) partition; the first HFS(+) partition of "sd0" is "sd0_hfs_a", the second is "sd0_hfs_b", etc. Disks without partition maps (such as floppies and ISO9660 CD-ROMs) are treated as though they consisted of a single HFS(+) partition, comprising the whole disk (e.g., "sd0_hfs_a").

Shared Mode

MacOS.app supports mounting HFS(+) volume(s) which are already mounted by Mac OS X Server. This mode of access is called Shared mode because all the files and folders on Shared volumes are simultaneously accessible from Mac OS applications running inside MacOS.app and Mac OS X Server applications running outside of it. Shared mode was chosen as the default file system access mode because it does not require the user to unmount a volume from one environment before mounting it in the other.

Although Shared mode access provides the highest level of interoperability between Mac OS and Mac OS X Server applications, it is not compatible with Mac OS applications that require low-level disk access. Mac OS productivity applications are not affected by this incompatibility since they access files and folders via the high-level interface provided by the File Manager. On the other hand, disk utility programs typically require low-level disk access. Examples of disk utilities that require Exclusive mode access are Disk First Aid, and Norton Disk Doctor. Examples of disk utilities that require SCSI mode access are Drive Setup, and FWB's Hard Disk Toolkit. None of these utilities will function correctly on a volume accessed in Shared mode.

Volumes accessed via Shared mode are slightly less compatible with Mac OS applications than if they were mounted in Exclusive or SCSI mode. But they are far more flexible because they allow you to concurrently share data between Mac OS applications running inside MacOS.app and Mac OS X Server applications running in the Mac OS X Server environment. This means that the files and folders you see in MacOS.app can also be seen from Mac OS X Server.

In Shared mode you should be able to run nearly all of the applications you run on a native Mac OS system. One small difference between volumes accessed via Shared mode is that the size of the underlying "disk" may not be reported accurately. For small HFS disks (like floppies), it might be overestimated by a few kilobytes and for large HFS+ disks (like multi-gigabyte hard drives) it might be underestimated by a few megabytes. This cosmetic difference should not have any adverse affect, since block-level access is not permitted on disks accessed via Shared mode.

In general, other incompatibilities and inconsistencies result from conflicts over shared resources. For example, if a Mac OS application running inside MacOS.app is accessing a file (or group of files) at the same time that a Mac OS X Server application is accessing them, there is a risk that they might make conflicting changes.

One place where this arises is in the process by which the Mac OS Finder rebuilds the Desktop Database. In Mac OS X Server, the Desktop Database is a shared resource that is managed by an independent server task (the "DesktopDB" server) and which fields requests from various clients, including MacOS.app. This works well and provides a centralized place for serializing access to the shared Desktop Database files. However the mechanism used by the Mac OS Finder for rebuilding the Desktop Database conflicts with the Desktop Database server. Consequently, rebuilding the Desktop Database on a Shared volume will not always have the desired effect. This issue will be addressed in a future Finder and MacOS.app. As a workaround you can switch the disk to Exclusive mode, rebuild the Desktop Database, and then switch the disk back to Shared mode. See the section on the "Blue Volume Mount Options" control panel for information on switching modes.

Another example of a shared resource conflict can be seen when attempting to eject a disk from one environment (the Workspace or the Finder) while it is in use by an application in the other environment. In this case, the ejection attempt may appear to succeed (i.e., the volume's icon may disappear from the desktop) but the disk might not be physically ejected from the disk drive. If this happens, the solution is to switch to the other environment and eject the disk from that environment as well (after closing any files that may be in use first, of course). Since Mac OS X Server cannot tell if individual files are open by Mac OS applications running inside MacOS.app, the Workspace will refuse to eject a disk that is mounted in MacOS.app, even if there are no individual files opened from that volume by Mac OS applications. Going in the other direction is a

little better; when you attempt to eject a removable disk from MacOS.app it will ask the Workspace to unmount any volumes mounted from that disk and to eject the disk. If there are no files open from that volume and no processes whose current working directory is set to a directory on that volume, then the disk will be automatically unmounted from Workspace and ejected - there will be no need to switch to the Workspace and eject the disk again.

Remember, having a Mac OS X Server application with its "current working directory" set to a folder on a disk marks that disk as "in use" the same way that having an open file does. For example, if you insert a floppy in the Workspace then in a Terminal window "cd" to some directory within the floppy, you will not be able to eject that floppy via MacOS.app.

Removable disks accessed via Shared mode are not ejected upon shutdown of MacOS.app (floppies are an exception).

How does Shared volume support work? MacOS.app contains the same File Manager code used by the native Mac OS with the addition of some logic that determines when a file system request is targeting an object on a Shared volume. These requests are passed over to the HFS(+) implementation in Mac OS X Server. The important thing to note is that this processing happens at the level of Mac OS File Manager requests, as opposed to disk driver requests or SCSI Manager requests. Thus, when you ask to "open" a file on a Shared volume, that request is sent to Mac OS X Server and is processed there. The results of the "open" in Mac OS X Server are passed back to MacOS.app and mapped into Mac OS "open" results. Then, a "read" from the newly opened file would be mapped into a Mac OS X Server "read" request and the results mapped in a Mac OS "read" result. The MacOS.app implementation of the Shared file system tries to map the file system requests and their results as closely as possible to native Mac OS. Applications should never know (or care) that they are running in the MacOS.app on a Shared volume, as long as they limit themselves to making File Manager requests and do not attempt to make disk driver or SCSI Manager requests.

The choice between Shared and Exclusive mode access can be made on a per-partition basis for disks with multiple HFS(+) partitions.

Exclusive Mode

MacOS.app supports mounting HFS(+) disk volumes in a mode that permits block-level access. This mode permits certain disk utilities (such as Disk First Aid and some operations in Disk Copy) to run that would not work with a disk accessed via Shared mode. This is called Exclusive mode because disks accessed by MacOS.app in this mode appear exclusively in MacOS.app and cannot be accessed by Mac OS X Server applications. You can request that a disk or partition be accessed via Exclusive mode by using the "Blue Volume Mount Options" control panel.

When Mac OS X Server first detects an HFS(+) disk partition (either when starting up or when a removable disk is inserted into a drive) it mounts it and notifies MacOS.app. MacOS.app is also notified about disks that are not recognized or mounted by Mac OS X Server. When MacOS.app notices a disk that has been mounted in Mac OS X Server for which the user has selected Exclusive mode, it asks Mac OS X Server to unmount the disk and then mounts it exclusively.

Because it remains under the control of the Mac OS X Server SCSI drivers, a disk accessed via Exclusive mode cannot be accessed via the Mac OS SCSI Manager, even if the underlying disk is a SCSI disk.

Volumes accessed in Exclusive mode can be read from and written to, regardless of the access rights of the user.

Disk image files like the supplied StartupDisk.img are always accessed via Exclusive mode.

The choice between Exclusive and Shared mode access can be made on a per-partition basis for disks with multiple HFS(+) partitions.

Removable disks accessed via Exclusive mode are usually ejected upon Shutdown or Restart of MacOS.app. CD-ROMs are an exception and are not ejected upon shutdown, in order to more closely mimic the behavior of Mac OS.

SCSI Mode

MacOS.app supports SCSI disk devices that are recognized by Mac OS X Server. MacOS.app provides a special compatibility mode for accessing these devices via the SCSI Manager, just as they would be accessed under the native Mac OS. This mode provides the highest level of compatibility with Mac OS disk utilities, especially with those that require SCSI access, like Drive Setup.

Like Exclusive mode, SCSI mode must be selected by using the "Blue Volume Mount Options" control panel. When MacOS.app first detects a disk for which SCSI mode has been selected, it attempts to unmount it from Mac OS X Server. If this succeeds, MacOS.app can access it in SCSI mode without fear of interference from Mac OS X Server applications.

Volumes accessed in SCSI mode can be read from and written to, regardless of the access rights of the user.

Unlike the choice between Shared and Exclusive mode access - which can be made on a per-partition basis for disks with multiple HFS(+) partitions - accessing a disk via SCSI mode precludes any other sort of access, either by Mac OS X Server or via Shared or Exclusive mode in MacOS.app. One consequence of this is that a disk containing a UFS file system partition that is mounted by Mac OS X Server cannot be accessed via SCSI mode in MacOS.app. For example, if your system has only one hard drive and has separate partitions for UFS and HFS(+) file systems, you will not be able to access the disk in SCSI mode.

Removable SCSI drives without media present will become reserved for SCSI mode access if probed via a SCSI disk utility like Drive Setup.

SCSI mode access is not available for ATAPI devices (which includes the internal CD-ROM and optional Zip drive on some Power Macintosh G3 models) or IDE/ATA devices (which include the internal disks on most non-Server Power Macintosh G3 models).

Switching Modes: The "Blue Volume Mount Options" Control Panel

In the "Apple Extras" folder of the supplied StartupDisk.img is the control panel to set the desired access mode for disks and disk partitions. Disks can be accessed in one of three modes (Shared, Exclusive, or SCSI), although not all disks will permit access in SCSI mode. A disk cannot be accessed in SCSI mode if it is not a SCSI disk (e.g., floppies, ATA/IDE/ATAPI disks). Nor can it be accessed in SCSI mode if there is a UFS file system mount point active on the disk at the time the mode switch is attempted (either when the control panel is launched or when MacOS.app is starting up).

Launching the "Blue Volume Mount Options" control panel displays a single dialog which can be dismissed by quitting the control panel or closing the window. Any changes that are made are stored immediately upon quitting the control panel, although most changes do not take effect until MacOS.app is restarted.

The control panel lists all the disk drives and disk partitions that it finds on the system, together with three columns of radio buttons, named after the three possible modes of operation: SCSI, Exclusive, and Shared. If a radio button does not appear in one of the columns, it means that the corresponding mode is not available for that drive (e.g., SCSI mode for an ATAPI CD-ROM drive). Radio buttons are used to convey the fact that each drive or partition can only be accessed in one mode at a time. For a brief explanation of how Mac OS X Server names disk devices, see the beginning of the "Disk Access Modes" section. If a disk partition is already mounted in Shared or Exclusive mode, it will appear in the control panel under that name (e.g., "sd0_hfs_a"). If it is a removable drive with no disk present, it will appear under the name of the drive (e.g., "sd0"). Finally, if it is being accessed via SCSI mode, it will appear labeled with its SCSI Bus and device ID (e.g., "Bus 0, ID 0"). In each case, these labels should correspond closely to what you will find in the "Where" string displayed in the Finder's "Get Info" dialog for that volume.

The same disk may appear under different names at different times in the "Blue Volume Mount Options" control panel depending on whether there is a disk in the drive. For example, the internal ATAPI CD-ROM drive on a Power Macintosh G3 will appear as "ATA drive sd0" when there is no CD-ROM in the drive, but as "HFS partition sd0_hfs_a" when a CD-ROM is in the drive.

If a disk has multiple HFS(+) partitions, they can be accessed in Shared or Exclusive mode independently from one another. In other words, the choice between Shared and Exclusive mode can be made on a per-partition basis. Similarly, Mac OS X Server can mount a UFS partition from a disk containing one or more HFS(+) partitions, each of which may be accessed in Shared or Exclusive mode. SCSI mode is different, though, because it requires complete control of all requests going to the disk. Therefore, selecting SCSI mode for one partition on a disk causes all the partitions on the disk to be accessed via SCSI mode. If you try this, you will see that the settings of the radio buttons automatically reflect this constraint. Similarly, you cannot select SCSI mode for a disk containing a mounted UFS file system. If you do select SCSI disk mode for a disk that contains an unmounted UFS file system, your selection will be honored. You will not be able to mount that UFS file system in Mac OS X Server while MacOS.app is accessing the disk in SCSI mode.

For fixed, non-removable disks, changes made via the "Blue Volume Mount Options" control panel will not take effect until MacOS.app is restarted. Removable disks are an exception to this rule: if you change the access mode for a removable disk then it will be accessed in that mode the next time you insert a disk in the drive. Consequently, you can quickly change the access mode for a removable disk by changing the setting in the control panel (and quitting it), ejecting the disk, and reinserting it - all without needing to restart MacOS.app.

There is one situation in which switching modes requires special care. When switching a non-removable disk to Shared mode from some other mode, you must shut down MacOS.app and wait for the Workspace to remount the disk on its desktop before re-launching MacOS.app. Otherwise, if you were to switch a disk to Shared mode and restart MacOS.app (e.g., from the Finder) then the Workspace might not have enough time to remount the disk before MacOS.app claimed it in Exclusive mode again. In this situation, the disk would not appear on the desktop of the Workspace and the "Where" string in the Finder's "Get Info" dialog for the disk would indicate "Exclusive". If this happens, the only way to get the Workspace to remount the disk for Shared access is to log out of the Workspace (after shutting down MacOS.app) and log back in again.

Currently, settings made via the "Blue Volume Mount Options" control panel are stored in the user's defaults database, although this might change in the future. Consequently, in a NetInfo environment, the same settings will be used for a user regardless of the machine they login to - beware. To see which disks have been set up in Exclusive mode, execute this command from the command line (i.e., in a Terminal window): "defaults read MacOS ExclusiveDisks". This "defaults" setting is a list consisting of device and/or individual partition names, separated by spaces. To see which disks have been set up in SCSI mode, execute this command at the command line: "defaults read MacOS SCSIDiskLoans". This list consists of ":" pairs, separated by spaces. If a disk or partition is not mentioned on either of these lists then MacOS.app will attempt to access it via Shared mode. In general, there should be no need to view these settings from the Mac OS X Server command line rather than with the "Blue Volume Mount Options" control panel. However, this information is provided because it might be useful for remote diagnosis and trouble-shooting.

The disk mode selections made via the "Blue Volume Mount Options" control panel are only requests. In some cases, it might not be possible to honor them and MacOS.app may mount a disk in a mode other than the one selected in the control panel. To find out what mode a volume is being accessed in, you can interpret the "Where" string displayed in the Finder's "Get Info" dialog for that volume, as described at the beginning of the "Disk Access Modes" section. For example, if Exclusive mode is selected for a disk partition but a Mac OS X Server application has a file from that partition open, then MacOS.app will not be able to get Exclusive access when it starts up. Rather than having the disk not appear in

MacOS.app in this situation, MacOS.app will fall back to mounting the disk in Shared mode.

Mac OS X "Disk Mounting" Preferences

There is a preference setting, "Disk Mounting", which can restrict MacOS.app's ability to unmount volumes from Mac OS X Server. In turn, this can prevent MacOS.app from ejecting removable disks and from accessing disks via Exclusive or SCSI mode.

To invoke the "Disk Mounting" preference panel, select it in the "Computer Settings" submenu of the Mac OS X Server Apple Menu. The panel includes some explanatory text. To change the panel's setting, you must be logged-in as root. Changes will not take effect until Mac OS X Server is restarted.

The default setting for a Server configuration is either "Fixed & removable disks" or "Only fixed disks". In a non-Server configuration where MacOS.app is going to be used extensively, it may be more convenient to select the "Only the startup disk" setting, for reasons that will be explained. However, this setting is not appropriate for a Server, because it means that files cannot be served from disks other than the startup disk unless someone is logged into the server. The other two settings are more appropriate for a Server because they permit files to be served from all disks attached at startup time, regardless of whether anyone is logged into the server.

In either of the Server modes you must be logged-in as root if you wish to use MacOS.app to eject removable disks or access disks via Exclusive or SCSI mode. This is a security precaution that is appropriate for a Server configuration, but might be overly restrictive for a Macintosh that is being used as a personal workstation, especially if it is shared between non-root users. If you select the "Only the startup disk" setting in the "Disk Mounting" preference panel (and restart Mac OS X Server), then disks other than the startup disk will be mounted upon login and unmount upon logout. As a result, the user that logs in will be able to use MacOS.app to unmount these disks, e.g. in order to eject a removable disk or to access a disk via Exclusive or SCSI mode.

Disk Drive Support

The following sections discuss the level of support provided for various kinds of disk media. Since some things apply to whole families of drives (e.g., SCSI drives) and some things apply to specific kinds of drives (e.g., CD-ROM drives), there is some overlap between the categories and you may need to read them all in order to find what you are looking for.

SCSI Disk Drives

SCSI disk drives can be accessed in Shared, Exclusive, or SCSI mode.

For more information on SCSI mode file system access, see the section on "SCSI Mode File System Access". For more information on switching the access mode, see the section on the "Blue Volume Mount Options" control panel.

SCSI disk devices (e.g., hard drives, CD-ROM drives, Zip drives, and Jaz drives) are supported, including those with multiple partitions. In Shared and Exclusive mode they behave like generic SCSI hard drives with the addition that disk-insertion detection and auto-ejection are supported. In Shared and Exclusive mode, special vendor-specific drivers (e.g., the Iomega Driver) are not loaded or used. If the drive has a manual-ejection button then it will be disabled while the disk is being accessed.

In SCSI mode, most third-party SCSI drivers are supported, including those that make possible special device-specific features (e.g., hardware write-protection or password protection). In this mode, MacOS.app supports the original SCSI Manager and SCSI Manager 4.3 with limitations. See the section on "Bugs and Compatibility Issues" for more details.

Mac OS X Server implements SCSI device arbitration. This means that only one client can send SCSI commands to a SCSI device at a time. Often, in the case of SCSI disks, this client is the Mac OS X Server file system. When MacOS.app is accessing a disk partition in Exclusive mode, then it is the client. For the purpose of SCSI mode access, MacOS.app can "see" any SCSI device not in use by Mac OS X Server (or any other client). In particular, removable disk drives with no media in place are always visible to MacOS.app and if probed will be accessed in SCSI mode until MacOS.app is shut down.

ATA/IDE/ATAPI Disk Drives

ATA/IDE/ATAPI drives can be accessed via Shared or Exclusive mode. They cannot be accessed via SCSI mode.

"ATA" and "IDE" are used interchangeably. The internal hard drives on most non-Server Power Macintosh G3 models are ATA/IDE drives. MacOS.app does not currently support the Mac OS ATA Manager. A future release may include an "ATA mode" similar to the existing "SCSI mode". "ATAPI" drives are special ATA/IDE drives with additional features. The internal CD-ROM and optional Zip drives on Power Macintosh G3 models are ATAPI drives.

Floppy Drives

Floppy drives can be accessed in Shared or Exclusive mode. They cannot be accessed in SCSI mode.

High Density (1.44 MB) floppies are fully supported. 800 KB floppies are supported read-only.

MacOS.app supports auto-detection and auto-ejection of floppies. Low-level initialization is only supported in Exclusive mode. If you insert a floppy that lacks a low-level format, it will be automatically accessed in Exclusive mode in order to permit you to initialize it. If, after initializing such a floppy, you wish to access it in Shared mode, you will need to eject it and reinsert it. See the section on the "Blue Volume Mount Options" control panel for instructions on how to change the mode. See the "Bugs and Compatibility Issues" section for other floppy issues.

Disk Image Files

Disk image files are volume images in Mac OS Disk Copy uncompressed format, stored in Mac OS X Server's UFS file system. They are always accessed in Exclusive mode. From the Mac OS X Server environment, they appear as large binary files whose name end in ".img". In the Mac OS environment, however, they appear as regular Mac OS volumes (with a special icon). By default, MacOS.app will startup from the disk image file in /Local/Library/MacOS/Users//StartupDisk.img. See the section "Working With Disk Image Files", below, for details.

CD-ROMs

CD-ROMs are supported in MacOS.app. They behave like locked SCSI hard drives when accessed via Shared or Exclusive mode. MacOS.app supports auto-detection and auto-ejection of CD-ROMs.

HFS(+) CDs can be accessed in Shared, Exclusive, or SCSI mode. DOS, ProDOS, PhotoCD, ISO 9660, and High Sierra CDs are automatically mounted in Exclusive mode, even if Shared mode is selected. They are also accessible in SCSI mode.

ISO9660 CDs are treated specially: they are mounted simultaneously in Mac OS X Server and in MacOS.app, but they are mounted in Exclusive mode in both environments. This may sound like a contradiction, but is possible because CD-ROMs are read-only media and there is no risk of writing inconsistent data or causing disk corruption. ISO9660 CD-ROMs are the only exception to the rule that disks appearing in MacOS.app in Exclusive mode do not appear in Mac OS X Server.

Only the first session of a multisession CD-ROM will be accessible in Shared or Exclusive mode. To access additional sessions the CD-ROM drive must be accessed in SCSI mode. See the section on the "Blue Volume Mount Options" control panel for instructions on how to change the mode.

Audio CDs are only accessible in SCSI mode. Audio playthrough is not supported, however.

If an Audio CD or any other CD in an unsupported format is inserted in Shared or Exclusive mode then the CD will automatically be ejected from the drive.

CD-ROMs are not ejected upon Shutdown or Restart of MacOS.app, even if accessed via Exclusive mode. This mimics the behavior of the native Mac OS.

DVD ROMs

DVD ROM disks are supported in Exclusive and SCSI modes. MacOS.app supports the UDF file system format that is used on these disks. DVD ROM movie playback is not supported in Mac OS X Server.

Working with Disk Image Files

Use of Disk Image Files

Although disk image files are used as default startup volumes in this release, they may not be the best choice for long-term use. More convenient startup volume options are available in this release which supports HFS(+) volumes that can be shared between Mac OS X Server and Mac OS.

You can use the Mac OS Startup Disk control panel to select a different startup volume. This can be very useful, but a few important steps are needed to properly setup a startup volume. If you plan to use this feature, be sure to read the "Startup Options" section below.

The StartupDisk.img created when you first launch MacOS.app is a relatively small startup volume (175 MB), which will not allow installing much software. It is suggested that you use available Mac OS partitions or create additional disk images to hold Mac OS applications and documents.

Even if you install applications elsewhere, as suggested, many applications also take up space in the System Folder on the startup disk. Enough

free space (about 40 MB) has been left for the System Folder additions of a few applications. However, you may eventually run out and be forced to enlarge your StartupDisk.img, as described below, or switch to startup from an HFS(+) partition.

Creating New Disk Image Files

At startup time, after finding the startup volume (StartupDisk.img by default), MacOS.app will search for and attempt to mount image files (files ending in ".img", but excluding StartupDisk.img) in the following Mac OS X Server directories:

```
/Local/Library/MacOS/Users/<user name>

~/Library/MacOS

/Local/Library/MacOS

/System/Library/MacOS
```

Note that the first two directories are private to a particular user ("~" means the current user's home directory), whereas the last two are global to all users of the machine.

MacOS.app respects the file permissions for disk images. If the user has only read permissions for the disk image file in the Mac OS X Server file system, then the image will appear locked in MacOS.app.

You can create new disk image files in Mac OS X Server by using Disk Copy in MacOS.app and creating the disk image on a shared volume, which can then be moved to one of the above directories. You can also create a disk image on a native Mac OS system and transfer the file to Mac OS X Server with "ftp" (or other utility).

Alternatively, you can use the provided "createimage" tool in the /usr/bin/ directory. It creates an empty image file that can be made available within MacOS.app. To use this tool, from a Terminal window (when logged in as the user who intends to use the image), execute:

```
createimage -mb num -o name
```

where "num" is the desired disk image size in MB and "name" is the pathname of the image file to be created, usually of the form:

```
"/Local/Library/MacOS/Users/<user name>/<name>.img".
```

For example:

```
createimage -mb 100 -o /Local/Library/MacOS/Users/me/mydata.img
```

The next time MacOS.app is started, Mac OS will present a dialog offering to initialize this new volume; you should allow the initialization to proceed.

Note: Issue Initializing Disk Image File

At the present time there is an issue that prevents MacOS.app from initializing the disk image file created by the createimage tool. A future release of MacOS.app or the createimage tool will correct this issue, but until they become available you should not use createimage to create new disk image files for use with MacOS.app, and should instead use one of the other methods for creating new disk image files described earlier.

Enlarging Your Startup Disk Image File

You can enlarge your StartupDisk.img by creating a new disk image with "createimage," and copying the contents of the startup disk to that new image. Perform the following steps to create a larger startup disk.

1. Make sure that MacOS.app is not running.

2. Create a new, larger, disk image using "createimage".

```
cd /Local/Library/MacOS/Users/<user name>

createimage -mb <size in MB> -o NewStartupDisk.img
```

3. Start MacOS.app.

4. Initialize the new volume when asked.

5. Copy the contents of the startup disk to the new volume.

6. Shut down MacOS.app.

7. Rename the original StartupDisk.img and rename your new disk image.

```
cd /Local/Library/MacOS/Users/<user name>

mv StartupDisk.img StartupDisk.img.old

mv NewStartupDisk.img StartupDisk.img
```

MacOS.app will now startup from your newly created startup disk.

When you are satisfied that the new startup disk image is OK, the old image may be removed to conserve disk space.

It is also possible to transfer image files to native Mac OS and modify their contents using Apple's Disk Copy utility. The correct file type and creator for image files are 'hdrv' and 'ddsk', respectively. These can be set when transferring if using Fetch, or afterwards via ResEdit or other utilities. The version of Disk Copy included with this release of MacOS.app supports opening disk image files with incorrect file types via drag and drop. Disk Copy will treat the data fork as a valid image only if the resource fork does not have any of the NDIF specific resources in it (or if there is no resource fork at all). So, if ftp is used to download just the data fork of a Disk Copy image file, Disk Copy should be able to mount it.

Startup Options

Startup

By default, MacOS.app starts up from your StartupDisk.img. If you have issues with your StartupDisk.img, see the section "Startup Disk Issues", below. If the currently selected Startup volume for MacOS.app does not support MacOS.app, a new StartupDisk.img will be created to allow proper startup.

If you wish, you may select an HFS(+) partition as your startup disk, using the Startup Disk control panel. You can even dual boot native Mac OS and MacOS.app from the same startup disk.

As with native Mac OS systems, you can hold the "C" key down to start up from the CD-ROM drive. This is done just after starting up MacOS.app, but before the gray screen appears.

Configuring a Startup Disk's System Folder

Beginning with Mac OS 8.5 no special setup is required; you just run the installer. For Mac OS 8.5, installation will require that the target disk is in Exclusive (or SCSI) mode during installation. In future versions of Mac OS it will be possible to perform an installation to a target disk in Shared mode as well.

Once your new startup disk is set up, select it using the Startup Disk control panel and then restart MacOS.app.

After setting your system to start up from a Mac OS partition, you may remove the StartupDisk.img file from the /Local/Library/MacOS/Users/ directory.

Startup Issues

If MacOS.app immediately quits on a user's first attempt to start up, check the ownership of the /Local/Library/MacOS/Users/ directory. If it is owned by root, change the ownership to using the chown command, then restart MacOS.app.

Startup Disk Issues

If you have an issue with your StartupDisk.img, MacOS.app can be forced to install a new StartupDisk.img. When starting MacOS.app, hold down the Command-Option-Shift keys. You will be given the option to modify your PRAM file. You must modify your PRAM file to proceed with fixing your startup disk issues. If you accidentally pressed the Command-Option-Shift keys, you should choose the Quit option.

After modifying your PRAM file, you will be given the option of deleting, using or renaming your current StartupDisk.img. If the disk image is corrupted and you don't want to mount it, but you don't want to delete it, be sure to remove the ".img" extension when renaming. Renaming a disk image across Mac OS X Server file system volumes (mount points) will result in a copy (rather than a rename). This will take a while.

If the "Copying StartupDisk.img" dialog is cancelled when MacOS.app is not in the foreground (i.e., the dialog is frontmost, but is not active), the "Cancel" button may appear pressed, but then doesn't release. Click anywhere in the dialog to complete the cancel operation.

Renaming a startup disk image across file system volumes when there is insufficient disk space available may cause Mac OS X Server to fail. Due to the large size of the disk images, caution should be used when maintaining several on your disks.

Copying StartupDisk.img Issues

If you receive the "Helper Copy Prolem. Exception raised during the write." alert while copying the StartupDisk.img, verify that there is sufficient disk space available for the copy (~ 175 M). This alert can be received if there is negative space available as reported by "df". As a non-root user, type "df -kl" in a Terminal window to get this information.

Bugs and Compatibility Issues

Killing MacOS.app from Mac OS X Server Workspace Process Menu

If you use the Mac OS X Server Workspace process menu to force-kill MacOS.app, an issue occurs if MacOS.app has gone through a restart since being launched by the Workspace. The issue occurs because whenever MacOS.app goes through a restart it gets different process IDs for all of the processes associated with MacOS.app. The force-kill option will shut down all of the MacOS.app windows, but the MacOS.app processes will not be killed because the kill signal will be sent to the original process IDs which no longer correspond to the running MacOS.app processes. Therefore, it will appear that MacOS.app has been killed, but you will not be able to launch a new MacOS.app. To work around this issue, you must manually kill the old MacOS.app processes from the command line using the kill command. You must first find the process ID of MacOS.app. You can do this by typing the following command from the command line:

```
ps -aux | grep MacOS
```

This will produce output that looks something like this:

```
machine ps -aux | grep MacOS

user 721 96.5 26.1 1.03G 33.4M ? R N 2:21 MacOS.app

user 752 0.2 0.1 924K 88K p1 U 0:00 grep MacOS
```

This output shows that the process ID for MacOS.app is 721 and the process ID for the grep command you just ran is 752. You must now kill the MacOS.app process by entering the following command (substitute the process ID of the MacOS.app process you are trying to kill for the process ID 721 as shown below):

```
kill -9 721
```

After killing the MacOS.app process in this way, you should be able to launch a new MacOS.app from the Workspace.

Tear Off Application Menu

The Mac OS Applications window that appears when the Applications menu is "torn off" does not list any Mac OS X Server applications that

normally appear in the MacOS.app Applications menu. To switch from MacOS.app to another Mac OS X Server application, you must use the Applications menu and not the tear-off window.

AppleShare File Server connection lost using TCP/IP

When running MacOS.app using the presently shipping version of Mac OS (System 8.5.1), there is an issue that may cause loss of connection to AppleShare File Servers that are connected via TCP/IP. The workaround for this issue is to connect to the server using the AppleTalk protocol instead. To do this, when selecting the File Server using the Chooser, hold down the Option key when you click on the OK button. This forces the system to connect via AppleTalk and not TCP/IP. This issue will be corrected in a future version of Mac OS.

Unable to read PC Zip disks

The present version of Mac OS X Server is unable to read PC Zip disks that have been formatted using the Iomega Tools. The issue does not occur if you initialize the Zip disk using MacOS.app by accessing the Zip drive using Exclusive mode and then initializing it by selecting the Finder's "Erase Disk" menu item.

Norton's CrashGuard

When running MacOS.app using the presently shipping version of Mac OS (System 8.5.1), Norton's CrashGuard INIT will not work in MacOS.app. A future version of Mac OS is expected to correct this issue.

Launching PowerPC Applications from Disks in Direct SCSI Mode

There is an issue that occasionally occurs when launching PowerPC Macintosh applications from disks accessed via direct SCSI mode. The issue causes MacOS.app to hang because of repeated timeouts attempting to access the disk. If you encounter this issue try changing the disk access to Exclusive mode. See the "Disk Access Modes" section for more details.

Symantec's ACT!

When running MacOS.app using the presently shipping version of Mac OS (System 8.5.1), Symantec's ACT! will not run properly in MacOS.app. The issue is due to a known incompatibility between MacOS.app and Mac OS 8.5.1 or earlier with regard to the GetSpecificHighLevelEvent() Toolbox call. An application that calls GetSpecificHighLevelEvent() directly will crash and possibly crash MacOS.app as well. A future version of Mac OS is expected to correct this issue.

Eudora Pro 4.1

When running this version of Eudora Pro on MacOS.app, the application crashes because it is making a power manager call which is not implemented in MacOS.app. A future version of Eudora Pro will correct this issue.

MacBench 5.0

When running the MacBench 5.0 "all" test (with CD in), MacOS.app will crash when it arrives at the Microsoft Word formatting stage. This issue is currently under investigation and should be corrected in a future version of MacOS.app.

Myth II

When launching Myth II under MacOS.app you may receive an error dialog saying "Myth does not have enough free memory to launch. Try closing open applications or turning on VM". This message is incorrect; the actual issue is due to the Myth application attempting to perform a dynamic screen resolution change that is not supported in MacOS.app. In order to run Myth II under MacOS.app you must first change the screen resolution in Mac OS X Server to 640x480 using the Preferences.app application, then launch MacOS.app with the new screen resolution and Myth II will run correctly.

Switching from MacOS.app to Mac OS X Server

Switching from MacOS.app to Mac OS X Server using command-return is not allowed during startup of MacOS.app. Attempts to do so prior to the Finder starting up will be ignored.

Locked files not owned by current user

MacOS.app runs the MacOS in a multiuser environment. Native MacOS runs in a single user environment. In the Mac OS X Server environment a user must be the owner of a file in order to unlock it. If you try to move a locked file or delete a locked file, owned by someone else in the underlying file system, you will get an "access privileges" error. You can workaround this limitation in several ways. 1) use the chown command to change the owner of the file 2) shutdown MacOS.app and login to the system as the owner of the file, then start up MacOS.app again 3) do the move/rename in a terminal window as root or after doing a su to the owner of the file.

Disk Icons

Disks formatted with 3rd party utilities and utilizing 3rd party drivers may appear on the desktop with a different icon than they would under the native Mac OS. For example, a removable Zip or Jaz disk may appear on the desktop as a generic hard drive icon.

Disk First Aid, Drive Setup, and the Mac OS installer

The Mac OS 8.5 installer will not function correctly when attempting to install Mac OS 8.5 onto a disk volume that is being accessed via Shared mode. This issue will be resolved in a future Mac OS release. If you need to install Mac OS 8.5 from within MacOS.app, switch the access mode of the target disk volume to Exclusive mode. See the "Disk Access Modes" section for more information.

Versions of Disk First Aid and the Mac OS installer currently shipping will not function correctly when their target is a disk accessed via Shared mode. Starting in a future version of Mac OS, Disk First Aid will simply report "no errors" for disks accessed via Shared mode without actually examining the disk. You can run the Mac OS X Server version of Disk First Aid (DiskFirstAid.app) or you can set the access mode of the target disk to Exclusive mode. See the "Disk Access Modes" section for more information.

In general, the Drive Setup application cannot be used on disk volumes that are accessed via Shared or Exclusive mode. It can only be used on SCSI disks (not ATA/IDE/ATAPI disks) that are accessed via SCSI mode. One of the things that the Mac OS installer does is ask Drive Setup to update the disk drivers of all the disks connected to your Macintosh. Disks that are being accessed via Shared or Exclusive mode will not be detected by Drive Setup and so will not have their drivers updated. Therefore, if you ever intend to boot your Macintosh into the native Mac OS, you should run Drive Setup manually from within the native Mac OS and select the "Update Drivers" menu option. Setting your disks to be accessed via SCSI mode from within MacOS.app might also work, but there are a few things that might prevent this from working as well as it would if you did it from within the native Mac OS: you might have non-SCSI disks on your system, or you might not be able to get SCSI mode access to all of your disks since at least one of them is used as the Mac OS X Server boot disk and therefore cannot be unmounted. See the "Disk Access Modes" section for more details.

If you have a 36 GB disk, do not format it with the version of Drive Setup that is located on your MacOS.app Startup disk. This could result in an improper format of the disk. Drive Setup 1.7.1, which can be found on the Mac OS X Server installation CD, should be used to format 36 GB disks.

Desktop Rebuild For Shared Mode Volumes

Desktop rebuilds on some volumes mounted in shared mode may take longer than the same rebuilds in native MacOS. It is recommended that if you must rebuild your DesktopDB, you do it in native MacOS or in MacOS.app using Exclusive mode. In fact, a rebuild of the DesktopDB in shared mode does not actually delete the old DesktopDB files (although it appears from the progress dialog that it does), so repair of any damaged entries may not be as complete as would be the case in Exclusive mode or in Native Mac OS.

MacOS Crashes After Improper Shutdown

There is an issue that only happens when running with Mac OS System 8.5 or 8.5.1, in which MacOS.app crashes on startup after being improperly shut down. This is a side effect of putting up the "Your Macintosh was improperly shut down" dialog and will be fixed in a future release of Mac OS. The workaround to this issue is to uncheck the "Shut Down Warning" checkbox in the General Controls control panel. Note that if you do this, not only will there no longer be a warning dialog after crashes, but Disk First Aid will not be automatically run in such cases. You

should run Disk First Aid to check the integrity of your file system after all improper shutdowns. There is a Mac OS X Server version of Disk First Aid (DiskFirstAid.app) that can be run on volumes shared with Mac OS X Server. In order for Disk First Aid in MacOS.app to run on a volume, it must be mounted in "Exclusive" mode (see the Disk Access Modes section). Or you can boot into native Mac OS and run Disk First Aid on the volume in question.

Runtime Performance

The runtime performance of MacOS.app is sensitive to other processes running on the Mac OS X Server, especially if these other processes consume the majority of "CPU" time. These types of processes are known as "CPU-bound" or "CPU-intensive" processes. The runtime performance of MacOS.app is highest when these types of processes are not running in Mac OS X Server.

File System Performance

In this release, Shared disk mode may be slower than other modes for some operations. If this is a concern, consider switching disk access modes or using disk images (which are always accessed in Exclusive mode). Disk access modes are discussed in detail in the "Disk Access Modes" section. Shared mode performance is expected to improve significantly in future releases.

NMI (Non-Maskable Interrupt)

On native Mac OS, using Command-Power to generate a NMI invokes the installed debugger (MacsBug) or invokes MicroBug if no debugger is installed. MicroBug is not currently supported in MacOS.app, so Command-Power with no debugger installed is ignored. When a debugger is installed, you may occasionally have to use Command-Power more than once to invoke the debugger. A current version of MacsBug is provided in the Apple Extras folder. Older versions are not compatible.

Mac OS X Server Workspace Logout

When logging out of Mac OS X Server with MacOS.app running, MacOS.app will come to the foreground with a dialog informing the user of the steps to safely shut down MacOS.app. The Workspace logout will be stopped. Upon shut down of MacOS.app, the user will again have to select Logout from the Workspace File menu. If MacOS.app was started from a shell window, it is not registered with the Mac OS X Server, so it will simply be killed during the logout process. This is why we don't recommend starting MacOS.app this way. Also note that if MacOS.app has gone through a restart since being launched by the Workspace, the process IDs for MacOS.app will have changed and the Workspace will not be able to contact it to initiate the safe shutdown dialog. This will also result in MacOS.app being killed during the logout process.

Sparse Virtual Memory

If Mac OS X Server runs out of disk space for virtual memory when MacOS.app is trying to allocate sparse virtual memory for an application, Mac OS will likely crash. This issue will be addressed in a future version of Mac OS X Server.

Aliases on Removable Disks

Mac OS has a limitation that sometimes causes aliases created on removable disks to fail when they are taken to a machine other than the one on which they were created. Because running MacOS.app is much like taking your disks created under native Mac OS and moving them to a different machine, this bug may manifest itself even though you did not physically move your disks to a different machine. This issue will be addressed in a future version of Mac OS.

Disk Copy Disk Images

Starting with Disk Copy version 6.3.3, it is possible to mount Disk Copy disk images from a Shared volume. However, it is not possible to create a disk image from an existing disk which is being accessed via Shared mode (i.e., using either of the "Create Image from Folder..." or "Create Image from Disk..." items in the "Image" menu of Disk Copy). If you are using an older version of Disk Copy to mount a disk image, or you are trying to create a disk image file from an existing disk, you will need to set that disk volume to be accessed via Exclusive mode. See the "Disk Access Modes" section for more information.

Disk images will only mount from shared volumes when the new Disk Copy driver (6.3.3) is loaded. This will happen if you run Disk Copy 6.3.3.

The newer driver will override older drivers and "stick" until Shutdown once loaded. This does mean that if you mount an SMI (Self Mounting Archive) created with an earlier version of Disk Copy before the new Driver has loaded, it will not work. The workaround is to run Disk Copy 6.3.3 once.

Disk Initialization

There are two kinds of "Disk Initialization": low-level formatting is device-specific and only need to be performed once for the life of the device, whereas high-level formatting simply writes an empty filesystem onto a device that already has a low-level format. The Finder's "Erase disk..." menu option usually only performs a high-level format, except for floppies, where it also causes a low-level format to be performed. The low-level formatting and partitioning of SCSI and ATA/IDE drives is performed by the Drive Setup application.

SCSI mode: The low-level formatting and partitioning of SCSI disks can only be achieved via Drive Setup for disks that are accessed via SCSI mode. Currently, this is not supported for ATA/IDE drives.

Exclusive mode: The Finder's "Erase disk..." menu option should function as expected for all volumes accessed via Exclusive mode. It will even perform a low-level format for floppies, as long as they are accessed via Exclusive mode.

Shared mode: Neither Drive Setup nor the Finder's "Erase disk..." menu option will function for disks accessed via Shared mode. You should not attempt to reformat or erase a volume that is being accessed via Shared mode. If you select a Shared disk and invoke the "Erase disk..." menu option and then select either the "Mac OS Standard" or "Mac OS Extended" format, then the operation will be aborted and you will get an error alert stating that the "Erasing the disk failed!", and the volume will be unmounted causing it to disappear from the desktop. If this happens, you can remount the volume via the Disk First Aid application - no data will be lost or altered.

The mouse cursor may freeze while performing the low-level format portion of the initialization process on a floppy. Switching to Mac OS X Server will be disabled until the formatting has completed, which may take several minutes.

MacOS.app ignores UFS disks by design, so you cannot reinitialize a UFS disk as HFS(+) with MacOS.app. However, you can do this via the native Mac OS.

NFS Sharing of Disk Images

Read-only disk images can be shared via NFS by instances of MacOS.app running on different machines, but read/write images must not be shared or image corruption will result. Note that startup disk images (StartupDisk.img) are always read/write. In the future these rules will be enforced by MacOS.app when NFS advisory locking (rpc.lockd) is available in Mac OS X Server; but for now don't try it. The sharing of all volume types works fine via Personal File Sharing and AppleShare.

Floppy Disk Can Prevent Startup

Floppy drives have traditionally been treated specially in the Mac OS startup process; the Mac OS always looks for a bootable floppy before attempting to start up from the disk chosen via the Startup Disk control panel. Originally, this was done in order to make it possible to start up a Macintosh with a floppy in case of hard disk corruption. Consequently, the Mac OS attempts to eject any non-bootable floppy that it finds in the drive during startup. MacOS.app inherits this behavior, but, unlike the native Mac OS, can be prevented from doing so by Mac OS X Server applications that may have files open on the floppy, not allowing it to be ejected from the drive. If this happens, MacOS.app will be unable to start up. If you would like to share files from a floppy between Mac OS X Server applications and MacOS.app applications, you should insert the floppy after starting up MacOS.app. Alternatively, you could eject it before launching MacOS.app and reinsert it after MacOS.app has started up.

Removable Media - Insertion and Ejection

When inserted, HFS(+) disks may take longer to mount in the Finder if accessed in Exclusive mode rather than in Shared mode. The extra delay results from the fact that HFS(+) disks are automatically mounted by Mac OS X Server and then need to be unmounted on behalf of MacOS.app in preparation for being mounted in Exclusive mode. This extra step essentially doubles the time required to mount a disk and may be noticeable - especially with slow media like floppy disks.

A request to eject a removable disk within MacOS.app may fail silently if the disk is shared with Mac OS X Server and files are open on the Mac OS X Server side (or a process has its current working directory set to a directory on the disk). In this situation, MacOS.app will behave as though the disk had been ejected (e.g., the disk's icon will disappear from the Finder's desktop), but the disk will not have been physically ejected from the drive. In this situation, you will have to switch to Mac OS X Server and eject the disk via the Workspace (after closing any open files, of course).

MacOS.app ejects all removable media upon shutdown if they are accessed via Exclusive mode, with the exception of the CD-ROM drive. If you

select a removable disk as the startup disk using the Startup Disk control panel and that disk is accessed via Exclusive mode, then you will have to quickly reinsert the disk into the drive during the restart.

File System Permissions on HFS(+) Volumes

The Mac OS X Server permissions model is enforced on volumes accessed in shared mode. The way permissions are enforced differs for HFS and HFS+ volumes, due to differences in their ability to store permission information. HFS volumes are unable to store permission information and therefore permissions have to be synthesized whenever they are needed. The permissions for the volume's mount point are used as the starting point for this synthesis (with appropriate differences for files versus folders). Moreover, when Mac OS X Server starts up, it mounts local volumes, setting the owner of these volumes to be root and the group to "macos". MacOS.app runs with an effective group id of "macos". By default, the macos group is set up to allow read/write access. Thus any user running MacOS.app will have access to all files and folders on HFS volumes mounted in shared mode.

HFS+ volumes mounted in shared mode behave similarly to HFS volumes with the exception of permissions that are explicitly set. Permissions are saved to disk on HFS+ volumes and are persistent on Mac OS X Server. However, native Mac OS completely ignores the permission information: it is neither enforced nor maintained. The HFS+ volume mount point will be owned by root and the group will be set to "macos", just as with HFS volumes. When a file is created the current user will be owner of the file and the group will be "macos". This will enable users in MacOS.app to access files as if they were running native MacOS. Please note that once permissions are set on HFS+ volumes they are honored when MacOS.app runs. So if you, or someone else, sets permissions in a terminal window, the above mechanism to allow MacOS.app access (via group macos) to files and folders will not allow access for someone without appropriate permissions to a file or folder. Unfortunately, MacOS was not designed to run in an environment where file access permissions might deny access. In most cases volumes mounted in shared mode will return "access denied" error codes that the Finder will pass along to the user when a permissions failure is noticed in the underlying file system. But there may be some cases where a confusing error may occur - so if you see strange error messages or odd behavior from an application on an HFS+ volume mounted in shared mode, keep permissions in mind.

As noted above, the group "macos" is a special group used to allow users of MacOS.app to access HFS and HFS+ file systems. If this group is removed or renamed, MacOS.app will not be able to access some local filesystems, and will refuse to run unless you are logged in as root.

Apple file services uses group permissions to control remote access to exported filesystems. If you set the group of an exported filesystem to anything other than "macos", then non-root users will not be able to access these filesystems in MacOS.app. To set the group for exported file systems using Remote Administration, click Disk & Share Points and click the disk or folder you want to share, then click Set Privileges.

Symbolic Links in Shared Mode

The R1.1 version of Mac OS X Server supports UNIX symbolic links in the Workspace. However, MacOS.app does not understand symbolic links on volumes mounted in shared mode. When a symbolic link is seen by the Finder or any other application in MacOS.app, the underlying file system always resolves the link. This would be like always resolving a MacOS alias. This behavior is not normal in a MacOS environment, so you may run into unpredictable results if you try to use symbolic links on volumes that are accessed in shared mode. One symptom you may see is a folder that does not contain any items or fewer items than there should be. If you must use symbolic links on volumes accessed by MacOS.app in shared mode, you may want to place the links in a well known directory (a folder called "symlinks", for example). Alternatively, name the symbolic link so it appears at the end of directory when sorted by name (zMyLink, for example). This issue will be fixed in a future version of Mac OS X Server.

Sound Input /Output

When MacOS.app starts up, it uses Mac OS X Server's sound preferences to initially set volume, balance, and mute levels. Changes to these preferences in MacOS.app will also change Mac OS X Server's preferences. While MacOS.app is running, changes to Mac OS X Server sound preferences will not change MacOS.app sound preferences.

Playing sound from an application running in Mac OS X Server at the same time an application is playing sound in MacOS.app may result in unpredictable results.

Sound input is not currently supported. This will affect speech recognition software.

Video Capture

Video capture is not currently supported.

Special Hardware Support

Some applications that require special hardware support, such as the Apple Video Player, will not work correctly under the BlueBox. These applications fail during startup and incorrectly post dialogs suggesting they could work if extensions are added to the System Folder.

Using Localized Disk Images

When starting up on the localized disk images available with MacOS.app, the default keyboard setting while running in Mac OS may differ from the keyboard setting in the Workspace. In Mac OS, this can be changed using the Keyboard control panel. Refer to the "Using different languages" section of Mac OS Help - available from the Help menu in the Finder.

Copy and Paste Between Mac OS and Mac OS X Server

Applications are advised to always use the Scrap Manager to access the Scrap. Direct scrap access may not behave correctly.

When copying data from MacOS.app to a Mac OS X Server application, it may take a noticeable period (up to several seconds) before the pasteboard is synchronized with data from the MacOS.app clipboard. If a paste is performed before this time (e.g., immediately after switching out of MacOS.app), the data may be incorrect, and the paste should be performed again.

MacOS.app supports the pasting of Japanese text between the Mac OS and Mac OS X Server environments. Starting with System 8.5.1, Japanese text can be copied to or from a Japanese localized Mac OS if MacOS.app was started with the Mac OS X Server Localization Preference set to Japanese.

System Folder Pieces

Just as with any Mac OS system, when applications are installed, they sometimes install resources into the System Folder on the startup volume. If you later change the startup volume or System Folders, those applications which require resources located in the System Folder, may not work as desired. In order for these applications to run correctly, you must either run the installer or manually move the appropriate pieces to the startup volume System Folder.

Serial

Serial is not supported in this release of MacOS.app; applications attempting to open either port will receive a notInitErr (-900). A future release of MacOS.app will have serial support.

Printing

Because serial is not yet supported, attempting to print to a serial-attached printer will hang MacOS.app.

Mouse Acceleration

MacOS.app uses Mac OS X Server's cursor acceleration for its own, so use Mac OS X Server's mouse preferences to configure cursor acceleration for MacOS.app. The Mac OS Mouse control panel will have no affect on cursor acceleration.

Video

Switching between Mac OS X Server and Mac OS can only happen at SystemTask() time. If Mac OS is hung, running a game which doesn't call SystemTask() or WaitNextEvent(), or sitting in MacsBug, you can't switch. You can still use Command-Shift-Q to force MacOS.app to quit. If this does not work, then the Mac OS X Server part of MacOS.app is hung and you will have to either telnet in from another machine and kill the MacOS.app process, or do a hard reboot of Mac OS X Server.

Similarly, if you switch to Mac OS X Server and then Mac OS hangs, you can't switch back. In that case, you must kill the MacOS.app process from Mac OS X Server. If MacOS.app drops into MacsBug while hidden, you may be able to unhide MacOS.app, but user input will not work. Command-Shift-Q should work.

The Video vertical retrace queue is hung off the System vertical retrace queue, and is therefore not synchronized with the actual monitor refresh

interval.

If for any reason MacOS.app causes the Mac OS X Server cursor to go away, you can restore it with the following command from a Terminal window:

```
/System/Applications/MacOS.app/MacOS -showcursor 50
```

Multiple monitors are now supported. MacOS.app does not support display repositioning (via the Monitors control panel). If you try it anyway, you will have issues. To undo your changes, remove the "Display Preferences" file from the Preferences folder in the System Folder, and restart MacOS.app.

Some Mac OS applications that draw directly to the screen may continue to do so even after switching from Mac OS to Mac OS X Server. The occurrence of this behavior may be limited by switching to the Finder before switching to Mac OS X Server.

Video mirroring in Mac OS is the feature where both monitors of a dual-monitor system display the same exact picture. Use of this feature is not fully supported in MacOS.app. If you use video mirroring, make sure to turn it off before switching to Mac OS X Server from the application menu.

Hardware video acceleration is not yet supported.

User Input

Direct ADB access is not supported. Applications that read directly from ADB devices and expect mouse ADB events will not work.

Command-Shift-Q will force MacOS.app to quit. This only works if Mac OS is hung, not if the Mac OS X Server part of MacOS.app is hung. See more details under "Video", above.

MacOS.app will intercept the Command-Return key sequence and use it to jump to Mac OS X Server. This is the same key combination that PC compatibility cards use. However, some Mac OS applications (like MPW) need this key combination for full functionality. To disable special handling of this key combination, type "defaults write MacOS ScreenToggleKey 0" on the command line of a Terminal window.

Date & Time

To change the date, time, or time zone, use Mac OS X Server's Preferences.app, rather than the Mac OS Date & Time control panel. Changes to the date, time, or time zone using the Mac OS control panel will be ignored. Other features of this control panel, such as date and time formats and the menu bar clock, are fully supported.

Canceling the "Copying StartupDisk.img" Dialog

If the "Copying StartupDisk.img" dialog is cancelled when MacOS.app is not in the foreground (i.e., the dialog is front most, but is not active), the "Cancel" button may appear pressed, but then doesn't release. Click anywhere in the dialog to complete the cancel operation.

SCSI Based Printers

MacOS.app does not support printing to the LaserWriter SC, or any other SCSI-based printer that requires the LaserWriter SC 7.0.1 driver.

Apple Software

The Mac OS Setup Assistant will allow the user to configure a local (serial) printer. If you do this and attempt to print to this printer, Mac OS will hang (see "Printing", above).

The Mac OS Setup Assistant on MacOS.app takes a little longer to configure printers than it does on native Mac OS. During this time do not select any menu or you will hang MacOS.app.

The Graphing Calculator has a bug which can cause a crash when running its "Mouse Control" demo and the application is located high in memory. This also happens on native Mac OS, but is much more common in MacOS.app.

The AppleCD Audio Player does not work in MacOS.app without additional configuration. Since the AppleCD Audio Player uses the SCSI Manager to find CD-ROM drives, this causes the application not to work in MacOS.app because CD-ROM drives are not mounted in SCSI mode by default in MacOS.app.

If the AppleCD Audio Player does not find at least one CD-ROM drive, it will return an error indicating that the CD-ROM drive is not responding. Some CD-ROM drives can be enabled to use direct SCSI access; see the section on the "Blue Volume Mount Options" control panel for instructions on how to switch the mode. If direct SCSI access is enabled on at least one CD-ROM drive, the AppleCD Audio Player will launch with no error and audio CDs can be played from MacOS.app, although audio playthrough is not supported.

Apple Video Player refuses to launch because MacOS.app does not currently support video capture.

When using the Extensions Manager, some of the installed Apple software is not a part of the "Mac OS 8.5 all" set (for example, "AppleScript" and "QuickTime"). This is normal when newer releases are installed.

Disk Copy prior to version 6.3.3 cannot mount images on a Mac OS volume that is in the Shared Access mode.

MacOS.app does not contain all the necessary Unicode converters to handle file and folder names on HFS+ volumes that were created on a native Mac OS machine using a system script other than Mac OS Roman. For example, if you take an HFS+ volume that was used on native Mac OS with the Japanese language kit installed, and you access it on Mac OS X Server, the file and folder names will appear garbled.

Third-Party Software

MacBench 4.0 crashes since it attempts to access hardware that is not supported by MacOS.app. MacBench 3.0 works correctly and MacBench 5.0 works with the exception of the issue noted previously in the paragraph entitled MacBench 5.0.

Networking modes promiscuous/raw are not supported in MacOS.app; therefore, applications such as Etherpeek are not supported.

Versions of CodeWarrior prior to the Pro 4 release do not support debugging; everything else seems to work. CodeWarrior Pro 4 (IDE 3.1) with version 1.3.6 of the MetroNub supports debugging and break/watch points.

RAM Doubler attempts to access the internals of Mac OS Virtual Memory and is therefore not compatible with MacOS.app.

Virtual PC attempts to access the internals of Mac OS Virtual Memory and is therefore not compatible with MacOS.app.

Disk Doubler Pro (and especially its Finder Menu feature) is not compatible with Mac OS 8.5 and therefore not with MacOS.app.

Speed Doubler causes MacOS.app to hang at startup, presumably because it attempts to modify undocumented Mac OS internals, and is therefore not compatible with MacOS.app.

The Disinfectant system extension (installed via the Protection menu of the Disinfectant application) should not be installed because it can cause some applications to quit with errors (such as Type 1 error). Conflict Catcher and Note Pad are particularly likely to crash when Disinfectant is present. Such errors are more likely to occur on MacOS.app than on native Mac OS because of the memory allocation scheme used in MacOS.app. Disinfectant is no longer supported by its developer, who recommends a full-featured virus protection program.

Adobe Persuasion 4.0's installer frequently fails with a bus error because of a bad memory access. Due to memory layout, this rarely occurs on native Mac OS, so a workaround is to run the installer there. Adobe has discontinued this product.

If drives formatted with FWB's Hard Disk Toolkit are mounted in "Shared" or "Exclusive" mode, any driver-level password protection will be ignored. Data that is encrypted will be inaccessible. Mounting these drives in "Direct SCSI" mode will re-enable password protection and access to encrypted data.

Descent II, like many other video games, uses SCSI Manager calls as part of its copy protection. By default, MacOS.app accesses SCSI disks via Shared mode. In both Shared and Exclusive mode, SCSI-level access is disallowed. The CD-ROM drive needs to be manually configured for direct access via SCSI mode. This can be done with the "Blue Volume Mount Options" application. However, the "Blue Volume Mount Options" application cannot set an ATA/IDE/ATAPI CD-ROM drive to direct SCSI mode. See the section on the "Blue Volume Mount Options" control panel for more information.

Mac OS X Server 1.x: About MailViewer

This article contains the Mac OS X Server release notes for the MailViewer application.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

New Features

The following new features are available in MailViewer but were not available in previous releases.

Multiple Account Support

You can now have multiple accounts configured in MailViewer. Using the Accounts preferences panel you can configure any number of POP or IMAP accounts. Each account needs a hostname, username and, optionally, a password set. If no password is given, MailViewer will prompt you when it is needed.

Each account must also have an "Account Directory" specified which is the directory that will be used to store local copies of mailboxes or where incoming POP messages are temporarily stored while fetching. For best performance, this directory should be on a local filesystem. If you are running MailViewer on multiple computers, they should not use the same directory for accounts.

In addition to any POP or IMAP accounts that you set up, there is a special account called "Local Mailboxes" which is always available to you. This account contains mailboxes that are located in the filesystem. The default location for these is ~/Mailboxes, although this can be changed. In this account there are 2 special mailboxes:

Active	This mailbox receives all incoming POP messages
Drafts	This mailbox is where messages get saved when you choose Mailbox->Drafts->Save in drafts

The first account listed in the Accounts list is the "primary" account. When MailViewer launches, it will try to open the "primary mailbox" of the primary account. If the first account listed is Local Mailboxes then the Active mailbox will be opened. If the first account listed is IMAP then the INBOX will be opened.

IMAP Accounts

MailViewer now supports IMAP accounts. By default, MailViewer will automatically cache the contents of IMAP mailboxes locally. You can change the caching behavior on the Accounts preferences panel. The other choices are to not cache any messages locally or to cache messages as they are read. Note, that if you have indexing turned on, the entire contents of the message will be read from the server (in order to index it) so you probably want to leave caching turned on.

Indexed Mailbox Searching

MailViewer now incorporates the Apple Information Access Toolkit (AIAT, also known as VTwin) to provide fully indexed mailbox support. There is a new Search Index panel which allows you to perform simple or complex (boolean) searches and display the relevance ranked results in a table. To create an index for a mailbox use the Mailbox->Indexing->Create Index menu item. Once an index has been created, this menu item will change to Remove Index which can be used to remove the index file for the current mailbox. To bring up the search panel, choose Mailbox->Indexing->Search Index.

To do a simple search, simply type one or more words in the text field on the search panel. The search will find any messages with one or more of the words in it. The results are shown in relevance ranked order which means that messages with the most and the closest matches are displayed first. The blue bar in the Rank column gives a percentage rank from 0% (no bar) to 100% (full bar). Also, AIAT matches "stems" of words, not exact words. Therefore, searching for "sleep" will find matches for "sleep", "sleepy", "sleepless", "sleeping", etc. Exact matches of "sleep" will be ranked higher but the other matches will still appear in the results. The search results will display the messages (up to 100) which match the search phrase. Double clicking on one of the resulting rows will display the message in the message viewer window. You can use the regular find panel to find the exact location in the message where the phrase(s) was found.

Boolean searches can be done using the modifiers "and", "or" and "not". Furthermore, logical groupings can be made by putting parentheses around terms. The following table shows some examples with a verbose description of the phrase:

Search Phrase	Meaning
Bill and Hillary	Find messages containing both of the words Bill and Hillary.

Bill or Hillary	Find messages containing either of the words Bill or Hillary.
Hillary not Bill	Find messages that contain the word Hillary but NOT the word Bill.
Bill and (Chelsea or Hillary)	Find messages that contain the word Bill and either (or both) Chelsea or Hillary
Bill and Hillary not (Monica or Paula)	Find messages that contain the words Bill and Hillary but do not contain either Monica or Paula.

Another thing to be aware of is that the AIAT engine uses a list of "stopwords" which are words which are not indexed. These are generally words which are commonly found in day to day language which are or little use when indexing. For example, "the", "also", "can" are all stopwords and will not be found if entered in the Search Phrase field. For the inclusive list of stopwords you can view the EnglishStopwords file which is located in /System/Library/Frameworks/Message.framework/Resources/EnglishStopwords.

When searching mailboxes, keep in mind that VTwin does not fully support non-ASCII characters so things like Japanese text will not be properly indexed. Most accented characters will be indexed properly although searching for these characters may return additional non-related messages. The messages containing the accented characters will typically be ranked much higher than the "false positives" and as a result will appear at the top of the results list.

There are a few preferences which control the indexing behavior. These can all be found on the Indexing Preferences Panel. The preferences are as follows:

Prompt about creating indexes	If this option is checked, MailViewer will ask you if you want to create an index whenever you create a new mailbox in the Mailboxes Panel or when you open a mailbox which is not currently indexed. The choices that you have are to click "Yes" meaning that you want to create an index of the contents immediately, click "No" meaning that you don't want to create an index at this time or click "No Forever" meaning that you never want to be asked again for this mailbox. If you click "No", MailViewer will ask you again the next time you open the mailbox. If you click "No Forever", you always have the option of manually indexing the mailbox at any time using the Create Index menu item. The default value is ON.
Maximum number of search results	This value controls the maximum number of rows the search panel will show. Increasing this number will increase the amount of time it takes to perform searches. The default value is 100.

Color Quotes:

MailViewer will now display text which is quoted in messages from other people in color. By default, the quote prefix is ">". Multiple levels of quotes (e.g. ">>", ">>>", ">>>>" and so on) get colored with different colors. This makes it easier to distinguish quoted text from the text from the person who sent the mail. There is a new Colors preference panel where you can turn this on and off, change the quote prefix and set the colors.

Remembering Open Mailboxes

In the Viewing preferences panel there is a new option called "Reopen previously open mailboxes". If this option is checked then any open mailbox windows at the time MailViewer quits will be automatically reopened when MailViewer is launched again.

Improved Unicode Support

Various improvements have been made to Unicode support in MailViewer. Among them are:

- Recognizing and generating the Windows-1250 and Windows-1252 character sets
- Properly decoding header values that have been encoded with specific character sets
- Improved ISO-2022-JP handling

Support for displaying MIME alternatives

If you have selected a message which contains MIME "alternatives" (different versions of the message, for example, plain text, rich text, HTML, etc), the MIME menu in the Message menu will become enabled. This menu lets you select between the "first alternative" (which is typically a plain text representation) and the "best alternative" (which is the richest representation that the sender was capable of creating). Showing of all

alternatives simultaneously or selecting intermediate alternatives is not currently implemented.

Paste As Quotation and Automatic Quoting

Under the Edit menu is a new menu item which will allow you to paste the contents of the pasteboard into a compose window as a quotation. The format of the quoted text can be changed using the Quoting preference panel. Also, if you have enabled the automatic quoting preference, messages will be quoted if you choose Reply or Reply All from the main window. If there is a selection in a message when you choose Reply or Reply All, only that portion of the message will be quoted.

MIME

MailViewer has advanced MIME capabilities such as inline images and attachments, multiple font styles and colors, and support for rulers.

MIME supports multiple alternative representations of a sent message and lets the receiver pick the most appropriate one. MailViewer generate two alternatives, one plain text and the other an "enriched" format that contains things such as font attributes, inline attachments, and text colors. If you deselect the "Send MIME alternatives" option, MailViewer sends only one representation (either plain text or enriched text) depending on the selection made in the format pop-up list in the Compose window.

When MailViewer receives messages with RTF text attachments it tries to display the contents of the messages inline in the body of the message (unless this feature is disabled).

MailViewer also supports a custom extension to MIME that allows the application to embed information about the ruler in the body of a message. Currently the only information embedded are the tabstop positions. This information is embedded in such a way that that clients that don't support the extension simply ignore it and display text indented by fixed-space tabs.

New Preferences Panel

Several preference options that weren't in the Mail application have been added to MailViewer. You should review each of the displays to verify your settings and set any new options to suit your needs. The new options are the following:

- User Information
  This display allows you to set your name and user name as it will appear in messages that you send. The default is to use the user name of the account you log in as, but you can change this to something else. The sample is only an approximation of how it will look to recipients of your mail because the receiving mail program controls the format. You can also specify a "reply-to" address that can be different than the account you are sending the mail from. This address is the one that most mail programs use when a user replies to messages; however, this behavior varies among clients.

- Viewing
  You use this display to customize various aspect of the mail viewer (the main window for each open mailbox). Here you can also set how often MailViewer should check for mail.

- Sending
  This display allows you to specify options used when you send mail. The most commonly supported delivery method is SMTP; your ISP or system administrator should provide the address of the SMTP host to use. You can disable warnings of messages over a certain size by either leaving the appropriate field blank or entering zero in it; even if you disable warnings, however, not all networks can deliver messages of any size. You should contact your ISP or system administrator if you experience problems with mail delivery that are due to the size of messages.

- Accounts
  This is where you can create your accounts and set options for each account type.

- Compose
  With this display you can specify the default format that MailViewer should use when you compose new messages. The display also allows you to control how you reply to messages. If you want to archive all outgoing messages automatically to a mailbox, you can enter the mailbox name in the appropriate field; if the mailbox doesn't exist, MailViewer creates it when you send the next message. To disable archiving for individual messages, hold down the Alternate key when you click the Deliver button.

- Quoting

If you want to quote the original text of messages automatically when you reply to or forward a message, you should check the appropriate checkbox in this display. You can also specify characteristics of the text included in the body of replied-to or forwarded messages for both plain text and rich text (MIME) messages. The format used is determined by the Format pop-up list in the Compose window when you click the Reply, Reply All, or Forward toolbar buttons or menu items.

- MIME
  In this display you can enable the option that allows you to receive messages with inline text attachments. You can also select the "Send MIME alternatives" option to have both plain text and enriched (MIME) text sent to recipients as alternative representations of your messages. If the ruler option is causing undesirable text in the body of messages sent by MailViewer, you can disable the option.

New Mailboxes Panel

The Mailboxes panel uses an outline view to display the contents of your accounts in a hierarchical manner. At the top level are all your accounts. You can create nested mailbox directories by typing a path in the New Mailbox panel. For example, entering "Meetings/Notes" in the New Mailbox panel would create a directory called Meetings in ~/Mailboxes with a Notes.mbox inside of it. You can create a new mailbox in an existing ~/Mailboxes subdirectory by selecting that directory in the mailboxes panel, typing a name, and clicking the New button.

If a mailbox has unread messages, the Mailboxes panel displays the mailbox name in bold face and shows the number of unread messages in parentheses after the mailbox name.

Display of Senders Image

When MailViewer displays an message it tries to find a TIFF file corresponding to the sender's e-mail address. The directories that MailViewer looks in are, in order:

1. Local/Library/Images/People
2. /System/Library/Images/People
3. ~/Library/Images/People

When it searches for a user's image, MailViewer use the From header's value and appends ".tiff" to the string. If it finds a match in any of the above directories, it displays that image in the upper right corner of the message viewer. For example, if MailViewer is displaying a message with a From address of "steve@apple.com", it looks for a file called "steve@apple.com.tiff" in one of the directories listed above.

It is common to populate a central directory on an NFS server with the images of a site's users and then mount that directory as /Local/Library/Images/People.

Known Issues

These issues are known to exist in the MailViewer application:

Issue	Garbled messages displayed
Description	Occasionally MailViewer displays messages incorrectly; it displays random characters or sometimes part of one message and part of another. This happens when the mailbox file and the table of contents file (**table_of_contents**) become out of sync.
Workaround	To fix the issue, open the affected mailbox and choose the Mailbox->Rebuild Mailbox menu item. Rebuilding the table of contents may change the appearance of your mailbox in two ways. The first is that messages previously marked as being deleted may appear as undeleted. The second is that messages which were previously unread may appear as having been read.

Issue	Messages accidentally left on POP server.

Description	If you fetch mail via a POP server and have the "Only fetch unseen messages" checked, some messages might be left on the server even though they are unseen. MailViewer determines if it has seen messages by keeping track of the Message-ID header of messages. Message-ID headers are supposed to be unique, but sometimes (typically as a result of mailing lists), some messages can have the same Message-ID. When MailViewer fetches mail from a POP server, it scans backwards (from newest to oldest) looking for a Message-ID that it's already seen. As soon as it finds one it stops looking and starts fetching from that message forward. Thus, if two messages on the POP server have the same Message-ID, the message behind the fetched one is not fetched.
Workaround	Periodically uncheck the "Only fetch unseen messages" option and have MailViewer fetch all messages on the server. If you don't have the "Delete messages on server" checked, a large number of new messages might be fetched. The suggested configuration is to have "Delete messages on server" checked and "Only fetch unseen messages" unchecked. This configuration avoids the issue altogether.

Issue	Can't change filtered headers.
Description	The original Mail application had a preference for indicating which headers to filter when reading messages. This preference has not yet been added to MailViewer's Preferences displays.
Workaround	Although the filtered-headers preference is not settable in a Preferences display, you can set it as a user default from the command line (using the Terminal application). The default name is "MailFilter" and the value is a string containing colon separated header names. For example, `defaults write MailViewer MailFilter "CC:Date"` causes the the suppression of the CC and Date headers when a message is displayed. Setting a default such as this overrides the default filtered headers, which is: "Content-Length:Content-Transfer-Encoding:Content-Type:Errors-To:Mime-Version:Received:References". Therefore, you might want to include these values in your custom setting.

Issue	Transferring messages using IMAP sometimes fails
Description	Sometimes when trying to transfer messages between two IMAP mailboxes, the transfer button stays in for a few seconds then pops back out. Unfortunately the mail does not get transferred and there is no error reported.
Workaround	Clicking the transfer button a second time will transfer the message.

Issue	MailViewer is showing a different IMAP message than the one I have selected
Description	If an IMAP mailbox is compacted (sometimes also called "expunged" or "compressed") by another mail client, the locally cached messages can get out of sequence. Because of this, MailViewer may show the body of one (cached) message with the header of the selected header.
Workaround	Removing the cache will clear this issue up. The cache of messages is kept in a directory called CachedMessages for each mailbox in an account. For example, if you have an account setup with an account directory of ~/MailAccounts/IMAPAccount and you are seeing this issue in the INBOX mailbox, you can remove the directory ~/MailAccounts/IMAPAccount/INBOX/CachedMessages. The next time the mailbox is opened, the cache will be checked for the message and since it no longer exists, MailViewer will retrieve it from the server.

Issue	List of message may get out of sync with IMAP server if multiple clients accessing the same mailbox
Description	When multiple clients access IMAP mailboxes simultaneously, the IMAP server generally notifies all clients about the changes. Unfortunately not all servers do this. As a result, the message attributes such as whether a message is read or deleted may not properly get updated when changes are made from a different IMAP client.
Workaround	Either closing and reopening the mailbox or choosing the Mailbox->Rebuild Mailbox menu item should resynchronize the message list.

Mac OS X Server 1.x: About Setting Preferences

These notes are for the Mac OS X Server Release of the User Preferences & Computer Settings panels.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

In this release, you can access commonly used preferences and settings panels via the Apple Menu. The User Preferences submenu contains preference panels that only affect the current user. The Computer Settings submenu contains settings that apply to all users of the machine. Not all available preferences and settings may appear in the submenus. To see a complete list of user preference panels, select More Preferences from the User Preferences submenu. Similarly, to see a complete list of computer settings panels, select More Settings from the Computer Settings submenu.

Appearance

The Desktop pattern selection user interface is greatly improved over the DR2 release. To quickly browse through all of the patterns using the keyboard, press Tab until the keyboard focus is on the pattern list. Press the up and down arrows to browse through the patterns.

To add your own personal patterns to the pattern list, create a DesktopPatterns folder in your home Library folder (~/Library). Any TIFF images that you place in the DesktopPatterns folder will appear in the pattern list.

Date & Time

The Network Time tab pane is not completely functional. If Network Time Synchronization is off, clicking the Start button will not turn it on, although the user interface will indicate otherwise. Network Time Synchronization will be activated the next time you restart, however.

Login Items

To remove an item from the Login Items window, you need only drag it out of the white area. You need not drag it all the way to the trash. In fact, dragging to the trash is not recommended as this action will cause the system to move the actual item to the trash.

Monitor

Changes to the color depth and resolution of your monitor will not take effect until you log out. By default, only the recommended resolutions are shown in the resolution list. Recommended resolutions are those resolutions that the system has determined are supported by your monitor. The system is not aware of all types of monitors, however, and may sometimes only show a severely limited subset of resolutions as recommended.

To enable the Show All resolutions feature, you can issue the following command in Terminal.

```
defaults write Preferences NSEnableShowAllDisplayModes YES
```

Be careful! If you attempt to use a resolution that is not supported by your monitor, your display may become unusable when you log out.

Multiple Monitors

The Multiple Monitors panel appears in the Computer Settings list of the Preferences & Settings window only when you have multiple monitors attached to your system. With the Multiple Monitors panel, you can arrange how the monitors are positioned relative to each other, and you can specify a main monitor. The main monitor is the monitor on which the login window and menu bar appear.

The Multiple Monitors panel is disabled by default on Power Macintosh computers because of a potential conflict with the Monitors & Sound control panel in the Mac OS environment.

Adventurous users can enable the Multiple Monitors panel by issuing the following command in Terminal:

```
defaults write NSGlobalDomain NSEnableMultipleMonitors YES
```

If you adjust the position of the monitors using the Multiple Monitors panel, you must not adjust the position of the monitors with the Monitors & Sound control panel in the Mac OS environment. Doing so will limit your mouse position to a single screen in the Mac OS environment.

Network

The Network panel now supports configuration of multiple network ports. Changes to the DNS search domains, name server addresses, FTP Server, Telnet Server, and IP Forwarding take effect immediately. All other changes require a restart to take effect.

Known Issues

The following issueshave been identified. When reporting bugs against the Preferences application, please identify the affected control panel and explicitly associate the bug with the installed release.

Keyboard Preferences

Issue	The Keyboard Panel does not type the correct extended characters in the text edit field. This also occurs in the Keyboard Panel invoked from the Localization Preference.
Problem	In the Keyboard Panel, some key caps are left highlighted when you type quickly in mixed case. This also occurs in the Keyboard Panel invoked from the Localization Preference.

Date and Time

These known issues with the Date and Time Preferences option also apply to the System Date & Time Settings panel in the Clock application.

Issue	Not all time zones in **/usr/share/zoneinfo** are shown in the pop-up menu.
Description	Do not attempt to manually set the **/etc/localtime** symbolic link to a time zone not shown in the pop-up menu.
Issue	The time field stops ticking when the system time is set to an earlier time using the BSD **date** command.
Workaround	Click on any day in the calendar. This causes the Revert and Set buttons to become enabled. Click the Revert button.

Monitor

Issue	If you use the keyboard navigation keys (tab, backtab and the arrow keys) to change the slider values, Preferences does not save the settings to the persistent user-defaults database. Thus, when you log out and log back in again, the values you had set in the previous session are not saved.
Workaround	Use the mouse to change the slider values.

Mac OS X Server 1.x: About QuickTime on Mac OS X Server

This file contains release notes for a Demonstration Release of QuickTime for Mac OS X Server.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

QuickTime enables editing and playback of multimedia content in a variety of video, sound, and graphic formats.

Notes Specific to this Release

The QuickTimePlayer application is a demonstration of QuickTime technology on MacOS X Server. It offers the following features:

- It is based on QuickTime 3.0.
- Media files can be opened and played.
- The player enables simple editing features.

Known Issues

- The version of QuickTime client included with Mac OS X Server does not currently support the Streaming features provided in QuickTime Streaming Server.
- QuickTime 3.0 third-party codecs are not supported in this release. This includes Sorensen Video, Indeo, QualComm PureVoice, and QDesign Music codec.
- Audio and video capture are not currently supported.
- There is no developer access to the QTML framework yet. This will be rectified in the Carbon release.
- Movies playing offscreen may display incorrectly when brought back onscreen. Use the Window Shade button to hide and show the window to redraw its contents.
- Files need to be world-readable to be viewed.
- Files at root (/) cannot be read. Try moving them into a directory.
- The movie thumb controller sometimes leaves portions of itself behind.
- If the QuickTimePlayer application crashes, sometimes the cursor is left hidden.
- Shift-click and drag in the movie controller doesn't work (use shift-click instead).
- QTVR, QD3D, and MPEG are not currently supported.
- Playing movies backwards may sometimes fail.
- PC graphics cards set to 4444 16-bit pixel format will not get correct visual results.
- Dual monitor setups are not supported.

Mac OS X Server 1.x: About Terminal

This article contains release notes for the the Mac OS X Server release of the Terminal application.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

For those familiar with Terminal in OpenStep for Mach, notes specific to this release are included. Also, a section is devoted to some of Terminal's less obvious features. Finally, this document includes information about Terminal's execution service, which is of interest mainly to developers.

New Features

The following new features have been added to the Terminal application in this release.

- Terminal has been moved to the directory /System/Administration (it used to live in /NextApps).
- Yellow Box Conversion and Macintosh User Interface: Terminal has been ported to use the Yellow Box APIs and to support the Macintosh menu layout and user interface. In addition, Terminal's execution service uses NSConnection-based ("new") Distributed Objects.
- Library Menu: You can configure Terminal to create a menu containing shortcuts for the terminal settings files in your ~/Library/Terminal directory. Enable this feature by executing the following command:

```
/usr/bin/defaults write Terminal LibraryMenu YES
```

  After restarting Terminal, the Shell>Library menu contains an item for each of the abovementioned files.

Known Issues

These new bugs have appeared since OpenStep for Mach 4.2.

Issue	The Page Up and Page Down keys don't work.
Issue	Characters lost when pasting text.
Description	Pasting a large body of text into a Terminal window will sometimes result in many of the characters being lost.

Terminal Features

- Saved Windows: You can save a window or set of windows to a file, thereby saving your preferred configurations. Everything about the windows is saved except the contents of the scrollback buffer; this includes the shell, the location of the window, and whether the window is miniaturized. When you choose the Save As command, you can decide whether all windows or just the main window is saved.
  Once a window is associated with a file, Save can be used to flush the settings out without seeing a Save Panel, just as with more conventional documents. However, if more than one window belongs with that file, all the relevant windows will be re-saved (the Save menu item indicates this by changing its label to Save Set). This convention allows you to open a set of windows, rearrange them, and type Command-s to save them back to the file.
  To have a file opened for you automatically each time you start up Terminal, you can either check a box in the Save As panel, or you can specify the filename in the Preferences panel under Startup options.
- Drag and Drop Support: Terminal can accept files dragged into a window: The appropriate filenames will be pasted, plus a space. Dragging an executable file onto Terminal's application icon results in that file being executed in a new Terminal window. If a directory is dragged, a new shell window is started with that directory as the working directory.
- Color Setting: You can drag and drop colors into Terminal windows to allow reverse video and other interesting settings. The color of the selection is settable, as are the color and size of the cursor.
- Activity Monitoring: Terminal tries to determine whether your shell windows are in active use by monitoring the processes inside them. If Terminal thinks something interesting is going on inside a window, it will mark the window with a broken X. You are prompted for confirmation before if you try to close a "busy" window or quit Terminal when there are busy windows.
  To make this evaluation, Terminal collects ps-type information about processes it considers relevant and applies a number of heuristics. Usually, Terminal considers shells and a few other garden-variety processes such as su to be innocuous and will not mark windows busy on their account. But there are exceptions; for example, if the distinguished process on the tty is a shell but it is actively running, the window will be dirty. You may designate additional "clean" command names (rlogin and telnet are common) in the preferences panel. If there are running processes on the terminal, the terminal might still be clean if the processes seem to be running in the background. But an interesting process that's the current process or that you've explicitly suspended with Control-z will always make the window dirty.
  The status of windows is checked only when it is likely to have changed. A back-off strategy prevents the probes from happening too often if the window seems constantly busy.
- Output Indication: When Terminal is hidden and one or more Terminal windows have received unviewed output, Terminal puts a blinking

icon in the menu bar. Also, Terminal window shades are marked as `dirty' when there is unviewed output.

- Accelerators: Two panels, Quick Title and New Command, provide an easy way to set the title on a window and to start up a new window running a designated command. Both of these panels would otherwise require use of the Preferences panel.
  Quick Title provides the current title of the window for you to edit; however, when you set the title this way Terminal won't update any of the information in the future. For example, if your window is titled "/bin/csh 80x24 ~/Term.term" and you edit that to include some text of your own choosing, the new title is treated as a string and won't reflect (for example) the size of the window should you change it. The preferences panel allows better control over this; you can mix your own material with Terminal's automatically updated information.
  New Command does use path searching when it execs your command, but since the path is just the default inherited from Workspace, it's utility is limited. You can add arguments, but shell metacharacters won't be handled correctly.
- A Tool for Creating New Terminal Windows: The program /usr/bin/terminal may be useful for opening new shell windows in the current (or another) directory. Without any arguments, it will open a new shell window in the current directory. (However, you may have a .login or .cshrc file which defeats this by changing to the user's home directory; you may wish to change this.) If a command is specified, terminal will, by default, run the command without a shell for fastest startup. If a shell is desired, it can be guaranteed by running the command with the -shell option. For usage information, type `/usr/bin/terminal -help'. For information on how this utility works, see the section Terminal's Execution Service below.
- Execution Service: Terminal publishes a Distributed Objects interface to allow it to execute commands on the behalf of other applications. See the section Terminal's Execution Service below.
- Settable Title Bar Text: A process can set the title bar of its terminal window by emitting the following string, without spaces or quotes:

```
ESC ] 0 ; "Title String" BEL
```

  where ESC is '!', and BEL is ''. The initial 0 may alternatively be a 2. The following csh script code (which can be added to a .cshrc file) shows one example of how you can set the title bar to a "clipped" version of the current directory. It also puts the hostname in the prompt in inverse video:

```
# begin csh script to set the title bar to the current working directory
set homedirectory = ~${user}
alias shortpwd 'pwd|sed -e "s|^/private||" -e "s|${homedirectory}|~${user}|"'
alias getTitle 'set titleString="`shortpwd|sed -e '\\''s|.*[^/]\\
(/[^/]*/[^/]*/[^/]*/[^/]*\\)|...\\1|'\\'' `"'
getTitle

if( ${?prompt} ) then
set hostNm=`hostname`
alias cd 'cd \\!*; getTitle ; echo -n "*]0;${titleString}*" ; set prompt = "*[7m${hostNm} >*[m "'
endif
cd .
#end csh script
```

- Terminal Services: You can configure Rhapsody Services to allow you to specify Unix commands to operate on text. (Like other OpenStep Services, these will be available when you're editing text in any application). Terminal services are dynamic and appear in other application's Services menu as soon as you define them. They can be edited by choosing 'Terminal Services...' under Terminal's Apple menu.
  When you specify the command associated with a service, you can use the tokens "%s" and "%p" to refer to the location where the selection and prompted input are inserted, respectively (prompted input is not requested unless this string appears in the command).

- Environment Variables: It is sometimes useful to know the tool that is providing the terminal emulation without changing the TERM environment variable. Terminal now sets 2 environment variables to provide this information to subprocesses:

```
TERM_PROGRAM=Apple_Terminal
TERM_PROGRAM_VERSION=99.99  (or something else...)
```

Terminal's Execution Service

Overview

The TSTerminalDOServices protocol, declared in the header **/System/Developer/Headers/Apps/TerminalDOProtocol.h**, allows applications to request that the Terminal application perform commands on their behalf. This is useful if a program wants to open up a shell window for the user to interact with, and it may be easier than setting up pipes and doing a fork/exec of a program yourself.

Terminal cannot provide services if it is not running. It may be necessary to use the Application Kit's NSWorkspace API to launch Terminal if the connection to Terminal fails.

You may run the commands in a window, in which case an integer window handle is returned to allow a window to be reused for subsequent commands, or the commands can performed in the background. In addition, you can specify the window's title, as well as the working directory and environment to be used when executing the command.

In the case of commands performed in the background only, you can pass in an NSData object whose data will be fed to the command's standard input, and if you pass in a pointer to an NSData, Terminal can hand you back the output of the command's standard output and standard error. If you pass a pointer to get these back, the data at the pointer should be nil before you invoke the command. Upon completion, the pointer points to an newly created NSData containing the output.

For details on the specific methods in the protocol, see the header file referenced above.

Security Considerations

By default, Terminal registers a port for the execution service with the Mach bootstrap server. This means that only processes descended from the Workspace application have access to this service. You can also have Terminal register this port with the Mach netname server, which allows access from other machines on the network. This is enabled by setting the default

```
/usr/bin/defaults write Terminal PublicDOServices YES
```

Important Note

Running with this default is a security hazard, as Terminal has no way of verifying who is making the remote connection.

Disabling the Service

Any user may disable this service by executing the following command:

```
/usr/bin/defaults write Terminal DisableDOServices YES
```

The superuser can disable it for all users on a given machine by giving this command:

```
touch /System/Administration/Terminal.app/.DisableDOServices
```

Sample Code and Client

The program **/usr/bin/terminal**, mentioned above in "A Tool for Creating New Terminal Windows," is a simple client which utilizes this protocol. The following is the source code for this program:

```
//
//  terminal.m
//
//        Sample client for Terminal.app's Distributed Objects services.
//        Copyright 1994-1997, Apple Computer, Inc. All rights reserved.
//
//
//    This program opens a terminal window in the current directory. It's installed
//    in /usr/bin/terminal.
//
//    Author: sam streeper
//    Updated by: Barry Locklear, Grant Baillie
//
//    To compile:
//
//      cc terminal.m -I/System/Developer/Headers -framework Foundation -o terminal
//
//    Usage:
// terminal [-shell] [-dir <dir>] [-noclose] [-env] [command]
//

#import <AppKit/AppKit.h>
#import <Foundation/Foundation.h>
#import <stdio.h>
#import <mach/mach.h>
#import <servers/bootstrap.h>
#import <Apps/TerminalDOProtocol.h>

static void usage(void) {
```

```
    fprintf(stderr,"terminal: open a new Terminal.app window\\n\\n");
    fprintf(stderr,"Usage: terminal [-shell] [-dir <dir>] [-noclose] [-env] [command]\\n");
    fprintf(stderr," -shell   - Run command from default shell\\n");
    fprintf(stderr," -dir     - Specify working directory (default is current)\\n");
    fprintf(stderr," -noclose - Retain window upon exit\\n");
    fprintf(stderr," -env     - Export current environment\\n");
    exit(-1);
}

static id<TSTerminalDOServices> lookupTerminalDOServer(void) {
    port_t sendMachPort;
    NSDistantObject *rootProxy = nil;

Mac OS X Server 1.x: About TextEdit

This article contains the Mac OS X Server release notes for the TextEdit application.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

- TextEdit is a small but powerful word-processing application based on the Yellow Box. It is written in Java, using the Java Yellow Box APIs. (The TextEdit application in Developer Release 1 was written in Objective-C using the Objective-C version of the same APIs.

Features

Most of TextEdit's word-processing capabilities come from the Yellow Box text system. These capabilities include:

- Editing rich text with graphics
- Support for Unicode and other encodings (if you have installed the Japanese package, you can read, write, and edit Japanese files on any Rhapsody system)
- Reading and writing RTF and reading HTML
- Ruler for setting paragraph properties
- Advanced typographical features such as hyphenation, kerning, ligatures, and baseline offsets
- Spell checking and correction
- Ability to access text services provided by other Yellow Box applications (such MailViewer's "Mail Text")

Additional features of TextEdit include:

- Ability to specify explicitly the character encoding to be used for each opened or saved file.
  Plain text files from different operating systems often use different encodings for international and special characters; if the default encoding choice that TextEdit uses when it opens a file turns out to be wrong, the user can specify the encoding through the pop-up menu in the Open panel. The default choice, "Automatic," tells TextEdit to use either the default eight-bit encoding of the system or Unicode.TextEdit can usually differentiate an eight-bit plain text file from a Unicode file, so it will choose the appropriate one.
  Similarly, the user can use the encoding pop-up menu in the Save panel to specify explicitly the encoding for a saved file. By default TextEdit uses the encoding used when the file was opened.
  You can set the default settings of these pop-ups items through the Preferences panel.

- Loading rich text files without interpreting the rich text; this allows the user to see and edit HTML tags (for instance) directly.
- A "Wrap to Page" mode, which presents the document wrapped to the current page size (as opposed to the window size), thus giving the user a simple WYSIWYG representation of the pages. This mode also allows zooming.
- A simple non-modal find panel with replace capability.
- Services ("Open File" and "Open Selection") to allow other applications to open files and text in TextEdit.
  TextEdit source files are installed with the development environment in the examples directory (on Rhapsody /System/Developer/Examples/Java/AppKit/TextEdit; on Windows in Developer/Examples/Java/AppKit/TextEdit under the directory where you installed the Yellow Box).

Known Issues

- If TextEdit or other Yellow Box Java applications fail to launch, the most likely cause is that your CLASSPATH environment variable is not correctly set. (This variable contains the path to the resources for the Java environment.) If this is the case, the application actually launches, but since it can't find its resources, it continues running without any graphical user interface. (You must kill the process with the Task Manager.)
  The workaround is to either remove this existing CLASSPATH (if you don't need it anymore), or to add the default class path for Yellow Box Java to the existing CLASSPATH. On Rhapsody, use the javaconfig command with the "DefaultClasspath" argument, for example:

  ```
  setenv CLASSPATH .:'javaconfig DefaultClasspath'
  ```

  On Windows NT, you can do this via the System control panel; on Windows 95 or 98, you need to edit your **autoexec.bat** file. The string to add (assuming you installed the Yellow Box in C:\\Apple) is:

  ```
  C:/Apple/Library/Java;C:/Apple/Library/JDK/lib/classes.zip
  ```

  Add this after the existing value, separated by a colon. Replace the two occurences of "C:/Apple" with the location you installed the Yellow Box in.

- If you wish to customize the list of encodings TextEdit shows in the Open panel popup, please copy the file DefaultEncodings.txt in TextEdit.app/Resources to Encodings.txt and add or delete the encodings you want. For a complete list of appropriate string encodings, see the header file NSString.h in the Foundation framework. For instance, WinLatin2 nor CP1251 encodings are "11" and "15".
- The complete list of encodings that are actually useful for TextEdit is: 2,3,4,5,8,9,10,11,12,13,14,15,30
- TextEdit can open HTML files, but doesn't save them. If you open an HTML file, edit, and then save, the file will be saved as an RTF or RTFD file. TextEdit will present you with a Save panel allowing you to specify a new name. Do not try to overwrite your HTML file, as TextEdit will simply end up appending "rtf"or "rtfd" to the name.

Mac OS X Server 1.x: About the Workspace Manager

This article contains the Mac OS X Server release notes for the Workspace Manager application.

Note: This document was installed by Mac OS X Server in /System/Documentation/ReadMe. For a list of other release notes see:
Article 30925: "**Mac OS X Server: Release Notes**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Key Differences from the Mac OS Finder

- You can move icons to the desktop from FileViewer windows. However, all icons placed on the desktop act like aliases instead of the original items. If an icon on the desktop represents an application, you can drop a document on it to launch (or activate) the application and have it open the document. You can remove items from the desktop by dragging them to the trash. This will remove the alias, not the original item that it pointed to.
- When you drag items between locations, you can force the creation of an alias rather than a copy by pressing the Control key while dragging. The Command key will force a move to be done, and the Option key will force a copy to be made. As on Mac OS, by default an item is copied if it crosses volumes or mount points and is otherwise moved.
- When renaming a file, you must press return after typing the new name or the change may not take effect. Also, you might see some display glitches in the filename if you delete characters while editing it.
- In this version of Mac OS X Server, a file's type is determined by the suffix in its name, instead of the type being invisibly stored by the filesystem as on Mac OS. If you rename a file and change its suffix, you might change which application will open it.
- You can use the option modifier key when double clicking a folder, or when using the tool bar, to reuse the same window instead of opening a new window.
- If you use the Goto panel (Command-g) to jump to a hidden directory (such as **.OpenStep**, or **/usr**), the File Manager shows all hidden files and directories whether you have selected the expert mode or not. To hide these files and directories again), then select the Update Viewers command in the Views menu (Command-u).

HFS Support

A significant addition since Developer Release 2 is support for HFS and HFS+ volumes. Because of the inherent differences in the capabilities of HFS and the Mac OS X Server filesystem (referred to as UFS below), there are issues that rise to the user level:

- When files are copied from HFS to UFS, any resource forks the files have will not be copied. In addition, their FinderInfo, including type and creator attributes, are lost as well. Workspace Manager will warn the user whenever they are moving files from HFS to UFS. It provides a "convert" option, which will try to add a suffix to the filename to match the type that it has under Mac OS.
- When files are copied from UFS to HFS, they will not have any type or creator when viewed by Mac OS.
- Files copied within HFS, or from one HFS volume to another, are handled correctly.
- When Workspace performs file manipulations on an HFS disk it does not consult or update the Desktop Database. This means that if you add, remove or move applications using Workspace and then use that disk under Mac OS, the Finder may report that it cannot find an application or not know about an application that you added. We recommend you do these operations under Mac OS (including MacOS.app, a.k.a. the "Blue Box").
- Although Workspace Manager hides hidden files on HFS volumes for non-expert users, this is not the case for hidden folders.

Known Issues

- Japanese users should consult the **Japanese-specific release notes**, especially regarding string encodings and HFS filesystems.
- Workspace Manager will not prevent the user from starting simultaneous file operations that may interfere with each other (e.g., copying a directory tree that is also being removed). Avoid initiating multiple operations that apply to the same set of files.
- Workspace is only able to initialize an entire disk, not an individual partition. Whenever Workspace initializes a disk, all data in all partitions of that disk is lost. To initialize a multi-partition disk, you will need to invoke the eject command on all but one partition, which unmounts them from the desktop. You may than select the last available partition, and choose the Initialize command.
- If an application fails to launch or crashes, there is no error message given by Workspace, other than an entry in the console window.
- It isn't possible to distinguish between HFS (Mac OS Standard) and HFS Plus (Mac OS Extended) disks in the Workspace.
- When presenting a message about an IDE hard disk, Workspace may refer to it as a SCSI disk. An example of this is seen on G3 systems with IDE/ATA disks.
- If you insert a removable disk that is locked and is either uninitialized or in a format Mac OS X Server does not recognize, it will be ejected without any error message. If you unlock the disk, you will be able to initialize it.
- Icons on the desktop (which are aliases) cannot be renamed. Furthermore, renaming the original of an alias on the desktop causes the desktop icon to disappear when the alias is next clicked because the original is not available.
- Filenames can contain spaces, but inserting spaces in filenames will probably produce issues within Project Builder projects.
- Sometimes creating a new folder can put you in "Expert mode", where files that are normally hidden become visible, such as Unix directories or files beginning with a period. If this happens, you can use the Update Viewers command to restore correct behavior (command-u).

- The Goto panel only works if you have a browser window open.

Mac OS X Server 1.x: Adding NetBoot Images To NetInfo

How do I add the NetBoot images to NetInfo?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The following script can be used to add the private_image_volume and shared_image_volume to NetInfo. This is useful if the NetInfo database (/etc/netinfo/local.db) is replaced with the template.

```
#!/bin/sh
# This script looks for Netboot HD.img and Applications HD.img in
# the following paths /<HFS+ Volume>/<HFS+ Volume>_NBS/SharedImages/
# If it finds them it adds the shared_image_volume and
# private_image_volume properties to netinfo
#
# Written by Scott George with help from Dieter Siegmund

##
# Constants
##
PrivateImage="NetBoot HD.img"
SharedImage="Applications HD.img"
PartialPath="_NBS/SharedImages/"

##
# get the list of mounted HFS volumes
##
mount -t hfs | while read line
do
   RealDrive=`echo $line | sed 's/.*on \\/\\(.*\\) (local)/\\1/'`
   ImagePath="/${RealDrive}/${RealDrive}${PartialPath}"
   if [ -e "${ImagePath}${PrivateImage}" ] && \\
      [ -e "${ImagePath}${SharedImage}" ]; then
niutil -createprop . /config/NetBootServer \\
          private_image_volume "${RealDrive}"
niutil -createprop . /config/NetBootServer \\
          shared_image_volume "${RealDrive}"
exit 0
   fi
done

echo "No images found"
exit 1
```

Mac OS X Server 1.x: How To Move A NetBoot Server

I need to move a NetBoot server to a new location that has a different network. How do I do that?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

To move a NetBoot server to a new location with a different network:

1. Delete all computers with name "macnc***" in Network Manager.
2. Delete all users "macnc***" from group g105 in Network Manager. You could also delete all the shadow images but this is not needed.
3. Open Network preferences and change TCP/IP settings for all cards as needed, and global settings.
4. Select BOOTP from the popup menu and change settings for all cards as needed.
5. Select AppleTalk from the popup menu and make changes as needed.
6. Restart the server computer.
7. If using Macintosh Manager, the netboot image must be updated to select the new server. Use NetBoot Desktop Admin to boot a client in private (persistent) mode, select the new server and save the images.

Use Macintosh Manager to edit Macintosh Management Server data.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Server Begins To Start Up Then Won‘t Respond

The computer begins to start up, then won't respond.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Mac OS X Server may be looking for a NetInfo server.

1. Disconnect the computer's Ethernet connection.
2. When asked if you want to continue in non-network mode, enter Y.
3. Log in as Administrator.
4. Open the Apple menu and choose Computer Settings, then choose Network.
5. In the NetInfo panel, make sure "Connect to parent NetInfo server at startup" is not selected.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: Monitor Screen Is Black

This article explains why the monitor on a computer with Mac OS X Server could be black.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Symptom
The monitor on a computer with Mac OS X Server is black.

Solutions

- Press any key. (The computer automatically dims the display when left idle; press a key to reset the display. You can set the dimming interval in Monitor Preferences.)
- Make sure the monitor is properly connected and adjusted. See the manual that came with your monitor for more information.
- Make sure the computer has a compatible video card. Shut down your computer by halting Mac OS X Server, then remove the video card. See article 60135 "**Mac OS X Server: Halting the Server and Restarting From the CD**." See article 30604 "**Mac OS X Server: System Requirements**" for information about compatible video cards.
- Make sure the resolution in Monitor Preferences is set to a resolution that works with the monitor.
    1. Shut down your computer by halting Mac OS X Server
    2. Restart the computer using the Mac OS X Server CD. This resets your monitor
    3. Use the System Disk application to select your Mac OS X Server hard disk as the startup disk
    4. Restart your computer

Published Date: Feb 18, 2012

Mac OS X Server 1.x: Halting The Server and Restarting From The CD

This article describes how to halt Mac OS X Server and restart from the CD-ROM disc.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Warning! This method of stopping Mac OS X Server may result in data loss or disk corruption. If possible, quit all applications and processes before following these instructions.

1. Put the Mac OS X Server CD in the CD-ROM drive's tray, but do not close the tray.
2. Press Control-Power, then press the H key. After a moment, your computer turns off.
3. Gently close the CD-ROM drive.
4. Turn on the computer, then hold down the C key. Continue holding the C key until you see the Welcome to Mac OS message.
5. Use the fsck command to check the root file system disk.

For more information on the fsck command, see :

Article 24501 "**Mac OS X Server: Why, When, and How to Run fsck for File System Maintenance.**"
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Can‘t Log In To Server

I can't log in to Mac OS X Server. What could cause that?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Try these solutions:

- Make sure you are entering your password correctly, using the same capitalization and punctuation that you originally used. If you still can't log in, log in as administrator and reset the password for your user account using Network Manager (open the Apple menu and choose Server Administration, then choose Network Manager).
- If you are using automatic login, temporarily bypass it by holding down the mouse button when you start up your computer. If you want to turn off automatic login, log in as the administrator, then open the Setup Assistant (open the Apple menu and choose Server Administration, then choose Assistant) and turn off the Automatic Login option.

Mac OS X Server 1.x and 10.x: Services Aren‘t Working

Mac OS X Services services don't seem to be working. What can I do?
This article has been archived and is no longer updated by Apple.
Try these solutions:

- Make sure the server is turned on.
- Check that one end of the Ethernet cable is plugged into the Ethernet port on the computer and the other end is plugged into a working Ethernet connector.
- Make sure the hard disk is working properly.
- Check Network configurations. See if the system can access devices or services on the network.
- Make sure the appropriate server processes are running.
- Restart the server.
- Use ProcessViewer to see what's working.
- If you've exhausted all solutions, you may need to reinstall Mac OS X Server or NetBoot server software. With Mac OS X Server 1.2 v3 or earlier, if you reinstall server software you will lose documents and data. If you have backed up your server, you can restore the data you backed up.
- For Mac OS X Server 10.0.3 check the logs via the log viewer or the in the Console.

Mac OS X Server: NetBoot Client Computer Won‘t Start Up

A NetBoot client computer won't start up. How can I fix that?
This article has been archived and is no longer updated by Apple.
Try these solutions:

- Sometimes a computer may not start up immediately because other computers are putting a heavy demand on the network. Wait a few minutes and try starting up again.
- Make sure that all the cables are properly connected, and that the computer and server are getting power. See the troubleshooting information that came with the client computer for more information.
- Check that one end of the Ethernet cable is plugged into the Ethernet port on the computer and the other end is plugged into a working Ethernet connector.
- Make sure the startup server program is running. If other computers can start up from the server, the server program is running. If other computers cannot start up, check the server's processes.
- Make sure you haven't exceeded the number of IP addresses assigned to your network. You check the IP address by logging in to the server and opening the Network Preferences panel.
- If you installed memory or an expansion card in the client computer, make sure it is installed properly.
- If you are using more than one Ethernet card, or you are using more than one port on a multiport Ethernet card, check to see if other computers using the same card or port can start up. If they can't, check to be sure the Ethernet port you set up on the server is the same port the client computer is connected to. It's easy to mistake Ethernet port 1 for Ethernet port 4 on a multiport card.
- If the computer has a local hard disk with a System Folder on it, disconnect the Ethernet cable and try to start up the computer from the local hard disk. Then reconnect the Ethernet cable and try to start up the computer from the network.

The following article may be helpful:

Article 60053 "**Mac OS X Server: Processes.**"

Mac OS X Server: NetBoot Log-in Screen Doesn‘t Appear

On a NetBoot client, you see the Mac OS desktop but the log-in screen doesn't appear.
This article has been archived and is no longer updated by Apple.
Make sure Network is selected as the startup disk in the Startup Disk control panel (for network-startup computers).
Published Date: Feb 18, 2012

Mac OS X Server: User Can‘t Log In To NetBoot Client

A user can't log in to a NetBoot client. What can I do to fix that?
This article has been archived and is no longer updated by Apple.
Try these solutions:

- Check to see if the user can log in to other computers. If the user can log in to other computers, then the computer the user can't log in to may be connected to a Macintosh Management server the user does not have an account on. If there is more than one Macintosh Management server, make sure the user has selected a server on which he or she has an account.
- Open Macintosh Manager and make sure the user is a member of at least one workgroup.
- Open Macintosh Manager and reset the user's password.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: How Many NetBoot Clients Can Connect to a Server

This article explains how many clients you can connect to a NetBoot server using Mac OS X Server versions 1.0 to 1.2.

Note: For server versions 10.0 and later, see technical document **107665**.
This article has been archived and is no longer updated by Apple.
The number of NetBoot client computers you can connect to your server depends on how your server is set up, as well as a number of other factors.

A NetBoot server that has this configuration can easily support 25 NetBoot client computers:

- Macintosh G3 computer with a 400 MHz processor
- 256 MB of RAM
- Two 9 GB hard disks
- Four-port, 100Base-T Ethernet card

If you want to use a server that has a different configurationor if you want to have more than 25 client computers, consider these factors:

- **Ethernet speed** - For optimum performance, use 100Base-T connections for both clients and server.
- **Hard disk capacity and number of NetBoot client computers** - The NetBoot server requires a minimum amount of hard disk space for each client connected to it. The amount of space depends on the size and configuration of the system image.
- **Hard disk capacity and number of users** - Each user needs storage space on a server for documents and preferences. If you have a large number of users, consider adding a separate file server to your network to store user documents. By default, users' documents and preferences are stored on the NetBoot server, but any AppleShare server can store this information. (You can set up where documents and preferences are stored using Macintosh Manager.)
- **Location of server and client** -- The startup server program only works with NetBoot client computers on the same subnet, and only one NetBoot server can run on a subnet. A NetBoot client computer can't start up using a server on a different subnet.
- **Number of Ethernet ports on the server** -- Distributing NetBoot clients over multiple Ethernet ports on your server offers a performance advantage. You can add ports by adding Ethernet cards, or by using several ports on a multiport Ethernet card. Each port must serve a distinct segment.

Note: As a client starts up from a NetBoot server, it creates a shadow image on the server's hard disk. Each NetBoot client's shadow image takes up the full space of a system disk image for a short time. The size of the server's shadow disk image increases and decreases as needed.

For more information on the NetBoot client's shadow image, please see article 60080: "**Mac OS X Server: NetBoot Theory of Operation.**"

Published Date: Feb 18, 2012

Mac OS X Server 1.x: UFS Backup Script

The provided script allows you to backup your UFS file systems on a Mac OS X Server computer. It attempts to filter out any file that is unmodified from your system installation. It does this by comparing the system's disk contents with the package receipts left by the Installer.app.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

This process takes a fair amount of time to examine the hard disk to determine what to write on the tape.

Limitations

- You must be logged in as the System Administrator to use the script.
- This script does not have any incremental backup functionality.
- Backups spanning multiple tapes has not been tested.

Steps to Create a backup

To create a backup archive do the following:

1. Make sure you are logged in as the System Administrator (root).
2. Start Terminal.app to get a BSD command shell window.
3. Use a text editor to create the backup script below. You only need to do this step the first time you wish to make a backup (or when a new backup script is released). Save the script as `/usr/local/bin/makebackup` and then make it executable (`chmod 754 /usr/local/bin/makebackup`).

```
#! /bin/sh
# simple backup script to copy all files listed in the system package receipts
# and added files to the specified destination
#
# usage: makebackup <destination>
#    where destination is typacally a tape backup device
#    e.g. makebackup /dev/rst0
#
# This is intended to be run only by the super-user
#
if [ `whoami` != root ]
then
echo "$0 is intended to be run by the System Administrator"
exit 1
fi

if [ "x$1" = "x" ]
then
echo usage: "$0 <destination>"
exit 1
fi

#
# remove modified files that are unnecessary to backup
# The list is:
#    /Network - network data residing on another machine
#    /private/Network - network data residing on another machine
#    /private/dev - special device files created at boot time
#    /private/var/run - runtime data create at boot time
#    /private/tmp - temporary directory cleaned up at boot time
#    AppKit and Foundation documentation is tweaked during post_install
#    /System/Library/Java diretiry is tweaked during post_install
#    /private/Devices - directory is mode changed during post_install
#    /Local/Library/Receipts - these are the package recepits and shouldn't be restored
#    precomp header files (*.p)
#    other misc. things
showmods -t --find-added | awk '{print $1}' | \\
sed -e '/^\\/Network\\//d' -e '/^\\/private\\/dev\\//d' \\
-e '/\\/private\\/dev$/d' \\
-e '/^\\/private\\/var\\/run\\//d' -e '/^\\/private\\/tmp\\//d' \\
-e '/^\\/private\\/var\\/run$/d' -e '/^\\/private\\/tmp$/d' \\
-e '/^\\/private\\/Network\\//d' \\
-e '/^\\/private\\/Network$/d' \\
-e '/^\\/System\\/Library\\/Frameworks\\/AppKit.framework\\/Versions\\/C\\/Resources\\/English.lproj\\/Documentation\\/Reference\\//d'
\\
-e
'/^\\/System\\/Library\\/Frameworks\\/Foundation.framework\\/Versions\\/C\\/Resources\\/English.lproj\\/Documentation\\/Reference\\//d'
\\
-e '/^\\/System\\/Library\\/Java$/d' \\
-e '/^\\/private\\/Devices$/d' \\
-e '/^\\/Local\\/Library\\/Receipts\\//d' \\
-e '/^\\/System\\/Library\\/Frameworks\\/.*\\.p$/d' \\
-e '/^\\/System\\/Library\\/CoreServices\\//d' \\
```

```
-e '/^\\/System\\/Library\\/Fonts\\/.default.fcache$/d' \\
-e '/^\\/System\\/Library\\/Frameworks\\/System.framework\\/Resources$/d' \\
-e '/^\\/System\\/Library\\/Frameworks\\/System.framework\\/Versions\\/Current$/d' \\
-e '/^\\/System\\/Library\\/PrivateFrameworks\\/Keyboard.framework\\/Resources$/d' \\
-e '/^\\/System\\/Library\\/PrivateFrameworks\\/Keyboard.framework\\/Versions\\/Current$/d' \\
-e '/^\\/private\\/var\\/vm\\//d' \\
-e '/^\\/Local\\/Applications\\/Internet\\/OmniWeb.app/d' \\
| pax -w -v -x cpio -f $1
```

4. Determine the BSD device name for your tape drive (generally /dev/rst0).
5. Run the backup script using the following command:

```
/usr/local/bin/makebackup tapeDevice
```

Where tapeDevice is the device name of your tape drive.

The makebackup script creates a cpio format archive. For more information on the cpio tape format please refer to the BSD manual pages for cpio(1) or pax(1). You can view these manual pages by using the following commands from a command line shell:

```
man cpio
man pax
```

Steps to Restore a Backup

To examine the list of files on the tape archive use the command:

```
pax -v -f tapeDevice
```

To restore files use the command:

```
pax -r -v -f tapeDevice <list of files to restore>
```

Where <list of files to restore> is a space separated list of file paths to extract from the tape archive. You must specify full file paths to restore and if the file paths contain spaces or other non-alphanumeric characters such as "*", you must enclose the file paths with single quotes (').

If you wish to restore all files from the backup, do not specify a list of files to restore.

Mac OS X Server: Macintosh Manager Cannot Add Preference Files

This article discusses adding a preference file in Macintosh Manager.
This article has been archived and is no longer updated by Apple.

Symptom

When running Macintosh Manager users unable to add a preference file from the Add File button in the Preferences tab under the Global tab.

Solution

Version 1.1 and later of the Macintosh Manager application no longer use the Add File button to add preference files.

The Macintosh Manager application works with drag and drop. You can drag any preference file from the System folder of the "NetBoot HD" volume (if you have started up the computer from a NetBoot server) or from the local hard disk to the Preferences window in Macintosh Manager.

You have to use drag and drop with Macintosh Manager to add a specific item to a workgroup if you use the Find button under the Items tab for a workgroup.

This occurs only if the Macintosh Manager Client has been installed. If you run the Macintosh Manager on a Macintosh without the Macintosh Manager Client installed, it does not occur.

Published Date: Feb 18, 2012

Mac OS X Server: Macintosh Manager - What Is System Access?

What does giving System Access to a user mean?
This article has been archived and is no longer updated by Apple.
System Access allows a user access to all items on the client computer, including the Finder and the System Folder. When a user with System Access logs in to a client computer, System Access appears as a choice in the workgroups log-in window.

Global Administrators always have System Access. Other users only have System Access if a Global Administrator sets this option for them.

Having System Access is equivalent to pressing command-shift-escape from the At Ease/Macintosh Manager login window. You will be required to enter an administrator's password if there is one.
Published Date: Feb 18, 2012

Mac OS X Server: About Apache 1.3.4

This article describes Apache 1.3.4.
This article has been archived and is no longer updated by Apple.
Apache 1.3.4 is incorporated into Mac OS X Server. Apache is a GNU licensed implementation of an HTTP 1.1 server. It can take advantage of many new features of Mac OS X Server including multilink multihoming, file level permissions, and scripting languages available at install (perl, TCL, sh, etc).

Apache makes use of CGI (common gateway interface) scripts to perform automated tasks on the server side. These scripts can be written in any of the supported scripting languages, and can utilize any system services, such as sendmail and ftp, that are accessible to the administrator. More information and add-ons to Apache are available from the ApacheGroup site at http://www.apache.org. Bug lists and reporting are also available through this site.

A/UX 2.0: "Disk Space" Value Depends on Login (6/93)

We set up a 160MB disk with a 57MB Root&Usr and a 70MB Usr partition. The 70MB partition is automatically mounted by an entry in fstab. Everything works, except there seems to be a major discrepancy in available space reported by the Finder.

When logging in as root, the Finder reports 3MB free on the Root&Usr and 16MB on the Usr partition (after double clicking the directory specified as the mount point in fstab). When logging in as any other user, the Finder reports less than 1MB on the Root&Usr partition and 7MB on the Usr partition. Why the discrepancy?

This article has been archived and is no longer updated by Apple.

The values you see for available free disk space (from either Finder or the "df" command), depend on whether you login as "root" or with a normal user (non-root) accounts. This is because A/UX 2.0 adopts UFS (Berkeley Fast File System) as the default root file system with minimum free-space threshold. UFS provides a mechanism that lets you specify the percentage of disk space RESERVED FROM USE by normal (non-root) users to reduce disk overhead and increase disk performance.

The percentage of space reserved for the Root file system shipped with A/UX 2.0 is about 5 percent, and the default percentage of space reserved for the non-root file system is 10 percent on the UFS file system. This is done via the -m option of the "newfs" command.

The point is that the root superuser has the privilege to see and use all free disk space, including the reserved space, but other users see only the AVAILABLE disk space.

If you really need some or all of the reserved disk space for normal use and don't care about disk performance, use the tunefs(1M) command with the -m minfree option to change the percentage of the reserved space on an unmounted UFS file system. For example, the command,

```
tunefs -m 0
```

sets a UFS file system without free-space threshold. However, the disk performance (throughput) is significantly lower than performance at the default 10 percent threshold.

For more information on Berkeley UFS, refer to newfs(1M) and tunefs(1M) manual pages.

Mac OS X Server: HTTP Server Does Not Start From the "On" Button

Turning the Network Settings Preferences 'on' in the control panel will not start the Apache web server. The 'off' button in the control panel turns the Apache HTTP service off, but the 'on' button does not start the server.
This article has been archived and is no longer updated by Apple.
You have to restart the server computer in order to start the web server from the control panel. The Apache server can also be started from the command line. This does not require restarting the server computer. To turn the HTTP server on without restarting, type this command in a Terminal window:

```
/usr/sbin/apachectl start
```

Mac OS X Server: Blue Volume Mount Options and SCSI Access

Blue Volume Mount Options do not always give exclusive or SCSI access to volumes in MacOS.app.
This article has been archived and is no longer updated by Apple.
In order to get exclusive or SCSI access for volumes in MacOS.app, the Workspace Manager must be able to unmount them in Mac OS X Server. This is not possible if there are files open on them in Mac OS X Server or if someone is logged into Apple File Services (AFP server).

There is one potential issue with the AFP server. If no one is logged into the server and MacOS.app is launched with volumes set for exclusive access, those volumes will be unmounted from MacOS.app. The result is that AFP users cannot mount these volumes until MacOS.app is shutdown. Again, if someone is already logged in, this will not happen.

Mac OS X Server: Disk Copy Reports Error -8812

When trying to mount a disk image in MacOS.app, Disk Copy reports an error -8812.

This article has been archived and is no longer updated by Apple.

Disk Copy needs special access to a volume to mount a disk image file. This can only be done on volumes that have either exclusive or SCSI access, not on volumes that are shared. Use the Blue Volume Mount Options application to change the access mode. Blue Volume Mount Options is located in the Apple Extras folder of the startup image that is created when MacOS.app is run the first time.

Mac OS X Server: Installers Look Like They Are Not Responding

During the installation of Mac OS X Server, there are several times where some software installers look like they are not responding (frozen). This is particularly visible during the installation of Web Objects and the NetBoot Server.
This article has been archived and is no longer updated by Apple.
The installer progress bar moves based on the number of files copied and not the number of bytes or running of post-install scripts. Therefore, when installing the NetBoot Server, the installer looks as though it has stopped when copying large Disk Copy image files.

The same is true when the Web Objects installer starts to run its post-installation scripts.

Let an installer run for 10 to 15 minutes before you restart the server computer or try to stop the installer.

Mac OS X Server: Delays in Starting up With 4-Port Ethernet Card

With a 4-port Ethernet card installed, the first few times Mac OS X Server starts up seem to take a long time.
This article has been archived and is no longer updated by Apple.
The default setting for the Ethernet ports is to use BootP. The computer will wait two minutes for a response from a BootP server. On a computer with a 4-port Ethernet card, this can result in a total of 10 minutes (two minutes for each port) of waiting. Once all the ports are configured properly or disabled if not in use, this will no longer occur.

Mac OS X Server 1.x: Tips for Importing Users With NetworkManager

This article gives tips on bulk importing users in Network Manager.
This article has been archived and is no longer updated by Apple.
NetworkManager has the ability to bulk import users from AppleShare IP but there are several issues to be aware of.

1. There is an option to fill in gaps in user numbers. Doing so results in all imported users having the same user number. To recover from this, uncheck this option and import again.
2. User numbers can be constrained. By default, Mac OS X Server uses numbers from 100 to 32767 but this range can be changed when importing users. The problem occurs when the range is smaller than the number of users being imported. In this case, when the maximum number is reached, the numbers will wrap and users will be imported with duplicate user numbers. To recover, adjust the range to the correct size and import again.
3. All imported users have login disabled. To correct this, select all the users and click the Uncheck the Login Disabled button.

Mac OS X Server: QuickTimePlayer.app Will Not Play All Movies

Some QuickTime movies will not play in QuickTimePlayer.app.
This article has been archived and is no longer updated by Apple.
QuickTimePlayer.app is based on Movie Player 2.5 so it will not play any movies that require Movie Player 3.0 or later. It is only a demonstration application.
Published Date: Feb 18, 2012

Mac OS X Server: SetupAssistant Can‘t Edit Existing Users

SetupAssistant does not allow editing of user information for users that already exist.
This article has been archived and is no longer updated by Apple.
SetupAssistant has the ability to create and edit users. However, it can only edit those users it is going to create. Once all the changes are made in SetupAssistant and saved, it will no longer be able to modify the user information on subsequent runs.

To edit user information for users that are already created, use the NetworkManager application.
Published Date: Feb 18, 2012

Mac OS X Server: SVGA Monitor Listed as VGA

When using an SVGA monitor, the Power Macintosh G3 (Blue and White) only lists 640 x 480 as a recommended resolution.
This article has been archived and is no longer updated by Apple.
This is normal behavior since an SVGA monitor does not have any sense pins like an Apple monitor does. To workaround this, select All in the Colors and Resolutions panel. Select a resolution that works with the SVGA monitor. Be sure to check the documentation for the SVGA monitor for compatible resolutions and scan rates as there is no easy way to recover from selecting one that is not compatible.

Changes to the color depth and resolution of your monitor will not take effect until you log out. By default, only the recommended resolutions are shown in the resolution list. Recommended resolutions are those resolutions that the system has determined are compatible with your monitor. The system is not aware of all types of monitors, however, and may sometimes only show a severely limited subset of resolutions as recommended.

To enable the Show All resolutions feature, you can type the following command in a Terminal window:

```
defaults write Preferences NSEnableShowAllDisplayModes YES
```

Warning: If you attempt to use a resolution that does not work with your monitor, your display may become unusable when you log out.

Mac OS X Server: Macintosh Manager - Access To Control Panels

I created a Panels and restricted Finder workgroup in Macintosh Manager with privileges to only see the Chooser. When I log in to the Panels or restricted Finder workgroup, I still have access to the Control Panels, Favorites, and Automated Tasks. They show up as generic icons.

In the Panels workgroup, selecting most of the items in the Control Panels, I get a warning message that I "do not have enough privileges." However, selecting Startup Disk allows me to change the current startup disk. Selecting TCP/IP gives me an error that there is "not enough memory..." Selecting QuickTime settings will freeze the client computer.

How can I fix this problem?
This article has been archived and is no longer updated by Apple.
Use the NetBoot Desktop Admin to make a private copy of the NetBoot HD and Applications HD volumes. Refer to the NetBoot Desktop Admin Read Me for instructions on how to do this.

Once you have write access to the NetBoot HD, navigate to the Apple Menu Items folder in the System folder. To fix the generic icons for the Control Panels, Favorites, and Automated Tasks, choose Get Info from the File menu (command+I) on each icon. Closing the Get Info window will restore the correct icon.

Follow the instructions for the NetBoot Desktop Admin to make the NetBoot HD and Applications HD read-only.

Now, when you login to the Panels workgroup, only the Chooser should be available.

Mac OS X Server 1.x: Description

This article contains the text of the Mac OS X Server1.x datasheet. Product specifications are subject to change without notice.

See also these articles:

Article 60162: "**Mac OS X Server 1.x: Features and Benefits**"
Article 60163: "**Mac OS X Server 1.x: Specifications**"
This article has been archived and is no longer updated by Apple.

Mac OS X Server 1.x

The powerful Internet and workgroup server.

Mac OS X Server 1.x software combines outstanding performance and robustness, the renowned Macintosh ease of use, and innovative services for the Internet and workgroups--all for one great price.

Mac OS X Server 1.x uses the same modern foundation that will power Mac OS X. Based on Mach 2.5 and BSD 4.4, this operating system is incredibly stable and scalable. It includes systemwide protected memory for crash-resistant computing, and full preemptive multitasking so that a single service can't monopolize the processor.

Two industry-leading Internet services--Apache and WebObjects developer tools--are included with Mac OS X Server 1.x. Apache is the world's most popular server for reliably delivering both static and dynamically generated HTML pages. Apache can be scaled from a workgroup Web server to a complex Internet site hosting multiple domains. Apple's standard implementation of Apache is fully integrated with Mac OS X Server 1.x, and the server software itself has been optimized to work with Apache.

WebObjects software is the most flexible and scalable way to develop and deploy network applications for viewing from any Web browser. It's a proven, industry-leading technology that currently runs thousands of mission-critical applications around the world. Included with Mac OS X Server 1.x are the WebObjects developer tools, which let you create your own WebObjects applications.

In addition to providing powerful Internet services, Mac OS X Server 1.x introduces a whole new way to manage your Macintosh workgroups. Apple's exciting NetBoot software enables a network of Macintosh computers to run from the same shared System Folder and applications volume stored on the NetBoot server. Just update the NetBoot server, and all the other computers have instant access to the new configuration.

Mac OS X Server 1.x also includes highly scalable file services capable of supporting thousands of open files, connecting to more than a thousand concurrent users, and pushing hundreds of megabits per second across the network.

Mac OS X Server 1.x: Powerful software for Internet services and Macintosh workgroups.

Key Features

Robust core operating system

- Kernel based on Mach 2.5 and BSD 4.4
- Protected memory
- Preemptive multitasking
- Native support for 100% Pure Java (JDK 1.1.6)

Industry-leading web server

- Standard implementation of Apache 1.3.4
- Optimized for fastest Apache performance
- Fully integrated single-button setup

Powerful application server

- WebObjects 4.0.1, the industry leader for developing and deploying flexible, scalable network applications
- 50-transaction-per-minute license
- Full suite of WebObjects development tools

Simple Macintosh workgroup management

- Apple's new NetBoot technology for managing Macintosh systems on a network
- Macintosh Management server software gives users secure access to their personal desktops, files, and applications from any Macintosh on the network
- NetBoot Desktop Admin software makes managing a network of Macintosh computers as easy as managing a single Macintosh

Scalable file services

- File services comparable to those in AppleShare IP
- Support for more than 4,000 open files per process and more than 1,000 simultaneous connections
- User and group information stored in NetInfo, a distributed network database
- Support for importing user information from AppleShare IP servers
- Ability to export the Apache documents directory to AppleShare clients
- Web-based Remote Administration tool for monitoring and changing server status, user and group lists, and mountable volumes

Mac OS X Server 1.x: Features and Benefits

This article contains the text of the Mac OS X Server 1.x datasheet. Product specifications are subject to change without notice.

See also the following articles:

Article 60161: "**Mac OS X Server 1.x: Description**"
Article 60163: "**Mac OS X Server 1.x: Specifications**"
This article has been archived and is no longer updated by Apple.

Features	Benefits
Robust core operating system	
Kernel based on Mach 2.5 and BSD 4.4	Provides an incredibly stable and scalable operating system based on open standards. Makes it easy to port applications from UNIX operating systems.
Protected memory	Helps prevent system crashes.
Preemptive multitasking	Prevents a single service from monopolizing the computer.
Native support for 100% Pure Java (JDK 1.1.6)	Runs any of the multitude of conformant Pure Java applications and applets. Integrates the Java runtime code with the native object model and threads for impressive performance and stability.
Industry-leading Web server	
Certified implementation of Apache 1.3.4	Brings the world's most popular web server to the Macintosh platform. Allows you to easily share Apache configuration files with or migrate them from other platforms. Supports easy updating to future releases from the Apache Group.
Optimized for Apache performance	Delivers performance outstripping any other Web server in its class.
Single-button setup	Gets your Web server up and running in minutes.
Powerful application server	
WebObjects 4.0.1 software	Provides the most flexible and scalable server for deploying network applications that can connect to multiple databases and generate HTML and Java user interfaces for a standard Web browser. Provides proven technology that has made WebObjects the most popular application server for the Internet and intranets, running some of the Web's most popular sites Lets you leverage hundreds of existing third-party WebObjects solutions previously developed for use on UNIX or Windows NT systems.
50-transaction-per-minute license	Allows you to evaluate WebObjects applications or deploy them in medium-size workgroups.
Full suite of WebObjects development tools	Enables you to create your own WebObjects applications. Enables you to assemble prebuilt components to create powerful reporting and electronic-commerce solutions. Includes the WebObjects Direct-to-Web feature to quickly enable access to SQL databases in a Web page
Simple Macintosh workgroup management	
Apple's new NetBoot technology	Enables you to configure and update systems on all your NetBoot-capable Macintosh computers by simply updating the NetBoot server once. Stores a single, consistent System Folder and application folders for all clients on a NetBoot server.

Macintosh Management server software	Enables individual users to securely access their system and applications, documents, and personal desktops from any NetBoot or non-NetBoot client. Lets you control access to your network by providing authentication services and system policy control.
NetBoot Desktop Admin software	Lets you administer the system and application resources used by NetBoot client computers from any NetBoot client. Allows you to manage all the Macintosh systems on your network as though they were a single computer.
Scalable file services	
File services comparable to those in AppleShare IP	Lets any AppleShare client access files over either TCP/IP or AppleTalk.
Support for more than 4,000 open files per process and 1,000 simultaneous connections	Enables you to provide file services to a large workgroup from a single Macintosh server.
Ability to share user and group information among different Mac OS X Server systems	Streamlines the updating of multiple servers.
Support for adding multiple users at one time from AppleShare IP servers	Speeds server configuration. Makes it easy to add a Mac OS X Server-based system to an existing AppleShare network.
Ability to export the Apache documents directory to AppleShare clients	Allows you to drag and drop files onto the Apache server from any Macintosh client.
Web-based Remote Administration tool	Provides easy-to-use file server management that you can access from any Java-capable Web browser.

Mac OS X Server 1.x: Specifications

This article contains the text of the Mac OS X Server 1.x datasheet. Product specifications are subject to change without notice.

See also the following articles:

Article 60161: "**Mac OS X Server 1.x: Description**"
Article 60162: "**Mac OS X Server 1.x: Features and Benefits**"
This article has been archived and is no longer updated by Apple.

Top Five Reasons to Get Mac OS X Server 1.x

1. Provide native Apache Web services on the Macintosh platform.
2. Develop and deploy cutting-edge network applications with WebObjects.
3. Control your network with NetBoot and Macintosh Management server software.
4. Scale your Apple file services to more than 1,000 users.
5. Support powerful third-party solutions for digital and print publishing.

Choosing between AppleShare IP and Mac OS X Server 1.x

AppleShare IP software provides file, print, Web, and mail services for Macintosh and Windows clients. Setup and management are done through an integrated and secure interface that makes AppleShare servers extremely easy to use.

Mac OS X Server 1.x does not provide all the same services as AppleShare IP, but does offer high scalability for Web serving and file sharing. It does not directly support Windows clients for file sharing, although any Web client can access its Web services.

If you need any of the following capabilities, you should choose Mac OS X Server 1.x:

- Configure and update multiple Macintosh systems from a single server
- Support more than 1,000 simultaneous Macintosh clients for file sharing
- Have a high-speed Apache Web server
- Implement a WebObjects application server

If, however, you need a general-purpose server that can support a mixed environment of Macintosh and Windows clients, you should choose AppleShare IP.

Ordering Information

Mac OS X Server 1.x
Order No. M7348Z/A (North American English)

Includes four CDs containing the following software:

- Base Mac OS X Server 1.x system
  - Mac OS X core operating system
  - Apache 1.3.4 web server
  - QuickTime Streaming Server (preview release)
  - Apple file services
  - Java 1.1.6
  - Perl 5.0
  - Sendmail 8.9
  - FTP
  - Telnet
  - NFS
  - Mac OS 8.5 compatibility environment
- WebObjects 4.0.1 development and deployment software*
- NetBoot server software*
  - Mac OS 8.5.1 client images for NetBoot client computers
  - NetBoot Desktop Admin
  - Macintosh Management client for non-NetBoot client computers
- Demo versions of third-party server solutions*
  - Avatar team collaboration and groupware from Avatar Works Limited
  - Cumulus media management system from Canto
  - Helios EtherShare, EtherShare OPI, PDF Handshake, and Print Preview file and print management software from HELIOS

Software GmbH
- Web Crossing and Web Crossing/Chat collaboration software from Lundeen & Associates
- RSCommerce electronic commerce suite from Running Start
- KeyServer client license management software from Sassafras Software
- CommuniGate Pro Internet messaging server from Stalker Software, Inc.
- FullPress file-sharing, WebNative, and OPI software from Xinet

*Includes electronic documentation for preinstalled software.

System Requirements

Mac OS X Server 1.x

- Power Macintosh G3 computer or Macintosh Server G3
- 64MB of RAM
- 1GB hard disk

Note: Mac OS X Server 1.x is not supported on iMac or PowerBook products.

NetBoot client computers

- Apple iMac or Power Macintosh G3 (Blue and White) computer
- 32MB of RAM

Macintosh Manager client computers

- A 68040 or PowerPC-based Macintosh computer
- Mac OS 8.1 or later
- 32MB of RAM

Important: Mac OS X Server 1.x uses a different file system, called Mac OS X Server Format, which supports POSIX file system semantics. This requires you to partition or reinitialize your existing Macintosh hard disk drives. Files that are shared with AppleShare or NetBoot clients must be stored on Mac OS Extended Format (HFS Plus) volumes.

Support Options

Apple is dedicated to providing support that meets the needs of our customers. Fee-based support for Mac OS X Server 1.x is offered on a per-incident basis or through an annual agreement. To purchase one of Apple's support products in the United States or Canada, please call 1 (888) 275-8258. In the United States and Canada, technical and administrative support is provided in English. For more information, visit http://www.apple.com/support.

Mac OS X Server 1.x: General FAQ

This article contains frequently asked questions (FAQ) regarding Mac OS X Server, with answers to those questions.

Also see the following articles:

Article 60166: "**Mac OS X Server: Operating System FAQ**"
Article 60167: "**Mac OS X Server: Services FAQ**"
Article 60168: "**Mac OS X Server: NetBoot/Macintosh Manager FAQ**"
Article 60169: "**Mac OS X Server: Hardware and Compatibility FAQ**"
Article 60170: "**Mac OS X Server: Pricing and Availability FAQ**"

This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. What is Mac OS X Server?
2. When will Mac OS X Server be available?
3. Who is the target customer for Mac OS X Server?
4. Is Mac OS X Server the same as Mac OS X?
5. How does Mac OS X Server differ from AppleShare IP?
6. How does Mac OS X Server provide greater scalability than AppleShare IP?
7. Will there be future releases of Mac OS X Server?
8. Will there be future releases of AppleShare IP?
9. Is Mac OS X Server the same as Rhapsody?

Question 1: What is Mac OS X Server?

Answer: Mac OS X Server is the first in a line of new server software products that demonstrate Apple's commitment to providing servers that meet the needs of its customers. The first release of Mac OS X Server will be available in both software and hardware configurations. It is the first product built on the core technology of Mac OS X, the desktop operating system scheduled for later in 1999. It includes innovative services such as the Apache Web server, WebObjects application server, NetBoot workgroup management technology, and Apple file services.

Question 2: When will Mac OS X Server be available?

Answer: Mac OS X Server is now available in English in the U.S. and Canada. It is scheduled to be available worldwide in April in English, Japanese, French, and German.

Question 3: Who is the target customer for Mac OS X Server?

Answer: Mac OS X Server is designed for use by experienced system and network administrators, who typically have had previous experience with configuring and managing at least two of the following:

- AppleShare IP and At Ease for Workgroups
- complicated networks, including routing between subnets
- other UNIX servers, such as Solaris and Linux

Question 4: Is Mac OS X Server the same as Mac OS X?

Answer: No. The client (end-user) version of the Mac OS X operating system is scheduled to be available at the end of the year. While Mac OS X will include an upgraded version of the Mac OS X Server foundation, the user experience will be optimized for a desktop operating system and will be more familiar to today's Mac OS users. Unlike Mac OS X, Mac OS X Server does not include Carbon, the technology for porting today's Macintosh applications to the new foundation.

Question 5: How does Mac OS X Server differ from AppleShare IP?

Answer: The two servers offer different types of services. AppleShare IP is a general-purpose server that includes a fully integrated set of services based on the familiar Mac OS 8.5 operating system, delivering high performance and exceptional ease of use. Some key services are unique to AppleShare IP, such as mail servers, SMB support, and firewalls.

Mac OS X Server provides innovative services such as an Apache Web server, WebObjects network application services, and the revolutionary new NetBoot server software for easily managing numerous Mac systems. Mac OS X Server provides these services through a powerful core

operating system, which features advanced capabilities such as preemptive multitasking and protected memory for incredible stability and scalability.

Question 6: How does Mac OS X Server provide greater scalability than AppleShare IP?

Answer: Mac OS X Server is scalable in three key ways:

- The core system supports over 1,000 simultaneous user connections.
- The multithreaded file system can handle over 4,000 open files per process.
- Advanced networking provides support for multiple 100-megabit-per-second network interface cards, allowing simultaneous full-bandwidth file transfers across multiple subnets.

Question 7: Will there be future releases of Mac OS X Server?

Answer: Yes. Mac OS X Server lays the foundation for Apple's future server software. Over time, it will incorporate features currently available only in AppleShare IP. Mac OS X Server will evolve into a bundle of services built on top of Mac OS X, similar to the way AppleShare IP currently builds services on top of Mac OS 8.

Question 8: Will there be future releases of AppleShare IP?

Answer: Yes, but Apple is not announcing specific plans at this time. Over time, Mac OS X Server will incorporate identical or equivalent functionality to AppleShare IP, and will become Apple's sole server operating system product.

Question 9: Is Mac OS X Server the same as Rhapsody?

Answer: No. Mac OS X Server leverages a number of the technologies formerly called Rhapsody. In addition, it includes some innovative services that were not part of the original Rhapsody project.

Mac OS X Server 1.x: Operating System FAQ

This article contains frequently asked questions (FAQ) regarding Mac OS X Server, with answers to those questions.

Please see the following article for further information:

Article 60165: "**Mac OS X Server: General FAQ**"
Article 60167: "**Mac OS X Server: Services FAQ**"
Article 60168: "**Mac OS X Server: NetBoot/Macintosh Manager FAQ**"
Article 60169: "**Mac OS X Server: Hardware and Compatibility FAQ**"
Article 60170: "**Mac OS X Server: Pricing and Availability FAQ**"

This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. What is the foundation for Mac OS X Server?
2. Is Mac OS X Server based on UNIX?
3. Does Mac OS X Server use a command line interface?
4. Does configuring Mac OS X Server require editing configuration files?
5. Does Mac OS X Server support remote administration?

Question 1: What is the foundation for Mac OS X Server?

Answer: Mac OS X Server is based on a Mach microkernel that roughly corresponds to Mach 2.5. This microkernel is integrated with an implementation of BSD 4.4 to provide a full UNIX-style operating environment.

Question 2: Is Mac OS X Server based on UNIX?

Answer: Mac OS X Server is built on UNIX technologies, implementing most of the POSIX APIs, which makes it easy to port UNIX applications, particularly those from a BSD heritage. The main exception is applications with a graphical user interface, because Mac OS X Server doesn't include the X Window System UI toolkits. Mac OS X Server is built around a graphical interface, unlike traditional UNIX systems that rely on the command line. However, Mac OS X Server cannot be called a UNIX operating system, as it does not fully comply with the POSIX and X/OPEN specifications required for use of the UNIX trademark.

Question 3: Does Mac OS X Server use a command line interface?

Answer: The primary interface is a Mac-like user interface, allowing administration with graphical tools. For administrators who prefer the command line interface or make use of Telnet/rlogin for remote administration, a Terminal application and several UNIX shells are included, as well as standard tools such as NFS, FTP, Perl, Tcl, and Emacs.

Question 4: Does configuring Mac OS X Server require editing configuration files?

Answer: No. Mac OS X Server provides a friendly Setup Assistant and a rich set of graphical administration tools. Editing configuration files is not required for basic use of any of the core ser vices. However, certain UNIX-derived services such as Apache use their existing configuration files for advanced administration.

Question 5: Does Mac OS X Server support remote administration?

Answer: Yes. There are currently several options, each suited to different purposes. Users, groups, and mountable volumes can be managed via a web-based remote-administration tool, similar to the one in AppleShare IP Configuration information can also be managed from another Mac OS X Server system via NetInfo, the built-in Network Directory Service. In addition, UNIX-savvy system administrators can enable Telnet for command line-based remote administration.

Article 60168: "**Mac OS X Server: NetBoot/Macintosh Manager FAQ**"
Article 60169: "**Mac OS X Server: Hardware and Compatibility FAQ**"
Article 60170: "**Mac OS X Server: Pricing and Availability FAQ**"

This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. What are the key services provided with Mac OS X Server?
2. What is Apache?
3. What version of Apache is included in Mac OS X Server?
4. How is Apache administered?
5. What is WebObjects?
6. Which version of WebObjects is included with Mac OS X Server?
7. What is NetBoot?
8. Which Apple file services are included?
9. Can I transfer my AppleShare IP user and group information to Mac OS X Server?
10. Does Mac OS X Server support Windows clients via SMB file sharing?

Question 1: What are the key services provided with Mac OS X Server?

Answer: There are four primary services in this release of Mac OS X Server:

- Apache Web server
- WebObjects network application services
- NetBoot and Macintosh Management server software for workgroup administration
- Apple file services

Question 2: What is Apache?

Answer: Apache is today's most popular Web server, serving over half of the public Web sites on the Internet. Apache is an open-source HTTP server developed by the Apache Group (www.apache.org). The Apache source code is freely available, making it easy for a large community to assist in fixing bugs, porting to new platforms, and customizing for special purposes.

Question 3: What version of Apache is included in Mac OS X Server?

Answer: Mac OS X Server includes Apache 1.3.4, the latest version available at the time of release. We are working with the Apache Group to ensure that future versions of Apache will compile directly on Mac OS X Server.

Question 4: How is Apache administered?

Answer: Basic administration of Apache is very simple. The Setup Assistant and control panels allow for easy on/off configuration, as well as selection of the hostname and documents director y. For advanced configuration, you can edit the same configuration files used by Apache on other platforms.

Question 5: What is WebObjects?

Answer: WebObjects is the industry's leading application server, with a flexible, scalable architecture for creating and deploying network applications. WebObjects provides a dynamic object-oriented environment for creating applications that can draw their data from a database server and run their user interface on any standard Web browser. WebObjects makes it easy to develop personalized content, e-commerce solutions, and MIS applications. For more information, see http://www.apple.com/webobjects.

Question 6: Which version of WebObjects is included with Mac OS X Server?

Answer: Mac OS X Server includes WebObjects 4.0.1, along with a 50-transaction-per-minute deployment license. The deployment license can be used for testing or for low-volume usage, or it can be upgraded for full-scale Internet deployment. For the first release of Mac OS X Server, Apple is including all of the WebObjects developer tools. These tools can be used for compiling WebObjects network applications, database client/server applications, or UNIX server applications. The included license covers only the tools and runtimes for Mac OS X Server. WebObjects 4.0.1 for Windows NT and UNIX platforms will continue to be available as a separate product.

Question 7: What is NetBoot?

Answer: NetBoot is a revolutionary Apple technology for managing Macintosh networks. System and user files are stored on the server, bypassing the local hard disk drive, thus making it easy to centrally administer large networks of Macintosh clients. Mac OS X Server also includes Macin-tosh Manager, a tool for allowing users of both NetBoot and non-NetBoot client computers to access their personal files and desktop environment from anywhere on the network.

Question 8: Which Apple file services are included?

Answer: Mac OS X Server includes a high-performance native implementation of AFP, the Apple File Protocol, allowing it to share HFS Plus volumes with any AppleShare client over TCP/IP or AppleTalk. You need to update client systems to the latest AppleShare client (version 3.8.2 or later) to ensure reliability, performance, and security. User, group, and mountable volume information can be managed remotely using a Web-based remote-administration tool, similar to the one in AppleShare IP.

Question 9: Can I transfer my AppleShare IP user and group information to Mac OS X Server?

Answer: Yes. AppleShare IP includes the ability to export its user information, which can then be imported into Mac OS X Server. It does not export passwords and group information, however, so that information will need to be recreated.

Question 10: Does Mac OS X Server support Windows clients via SMB file sharing?

Answer: This version does not provide integrated support for native Windows (SMB) file sharing. However, Mac OS X Server can support Windows clients that function as AppleShare clients. Several third-party solutions should be available, including the free SAMBA server.

Mac OS X Server 1.x: NetBoot/Macintosh Manager FAQ, Part I

This article contains frequently asked questions about Mac OS X Server, with answers to those questions.

For Part II of this article, please see article 88109: "**Mac OS X Server: NetBoot/Macintosh Manager FAQ, Part II**"

See also:

Article 60165: "**Mac OS X Server: General FAQ**"
Article 60166: "**Mac OS X Server: Operating System FAQ**"
Article 60167: "**Mac OS X Server: Services FAQ**"
Article 60169: "**Mac OS X Server: Hardware and Compatibility FAQ**"
Article 60170: "**Mac OS X Server: Pricing and Availability FAQ**"

This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. What are the advantages of the NetBoot server?
2. Who should use the NetBoot server?
3. What components are included with the NetBoot server?
4. What types of Macintosh computers can I use with the NetBoot server?
5. What is Macintosh Manager, and how does it interact with At Ease for Workgroups?
6. Can I manage non-NetBoot clients with Macintosh Manager?
7. Can other Mac systems be upgraded to support NetBoot?
8. How does a Macintosh start up from the network?
9. How do I set up a Macintosh to start up from the server?
10. What version of the Mac OS runs on a NetBoot client?

Question 1: What are the advantages of the NetBoot server?

Answer: The NetBoot server makes it easy to manage a network of Macintosh computers. With a traditional network, adding an application or changing a system component requires administrators to physically update every computer on the network. NetBoot-capable Macintosh computers--called NetBoot clients--share the same System Folder and applications stored on the NetBoot server. Updating the shared System Folder or adding an application to the server immediately updates every NetBoot client on the network. The shared system components are protected to prevent users from corrupting the system. Since new NetBoot client computers on the network don't require any configuration, adding one system or creating a new lab of computers is fast and simple. Users also have access to their applications, documents, and personal desktop environment at any Macintosh on the network.

Question 2: Who should use the NetBoot server?

Answer: The NetBoot server is designed for any organization using Macintosh computers on a network. It helps educators bring technology to the classroom with low-cost, easy-to-manage computers like the iMac. NetBoot helps educators who want to:

- Improve the student to computer ratio.
- Achieve technology goals under tight fiscal constraints.
- Reduce the cost of managing their computing infrastructure.
- Use existing technology resources.

The NetBoot server is also ideal for business customers with Macintosh networks, particularly those who want to replace data entry or editorial terminals. It allows them to reduce their computer costs through low-cost Macintosh hardware and reduced administration requirements.

Question 3: What components are included with the NetBoot server?

Answer: The NetBoot server runs on Macintosh G3 computers with the Mac OS X Server operating system. NetBoot includes:

- Three server applications: a BootP server, an AFP server, and a Macintosh Management server.
- Mac OS 8.5.1 system software and accompanying applications used by the NetBoot client computers.
- Two administration applications: NetBoot Desktop Admin for installing applications for use by NetBoot clients, and Macintosh Manager for administering users and groups on the network.

Question 4: What types of Macintosh computers can I use with the NetBoot server?

Answer: All iMac computers and the new Power Macintosh G3 (Blue and White) computers introduced at Macworld 1999 have the necessary hardware and firmware needed to support NetBoot. Future Macintosh computers may also be NetBoot-capable.

Question 5: What is Macintosh Manager, and how does it interact with At Ease for Workgroups?

Answer: Macintosh Manager is a technology for storing the user's computing environment on the server, so that the user can obtain his or her environment from any Macintosh on the network. This can include application preferences, desktop patterns, and fonts, depending on the level of customization allowed by the administrator. Macintosh Manager is based on, and can be considered a replacement for, At Ease for Workgroups, an earlier Apple product available only to education customers. Macintosh Manager on Mac OS X Server systems can serve both NetBoot and non-NetBoot clients.

Question 6: Can I manage non-NetBoot clients with Macintosh Manager?

Answer: Yes. An installer is provided that adds the necessary components to non-NetBoot Macintosh computers.

Question 7: Can other Mac systems be upgraded to support NetBoot?

Answer: No. Systems that are not NetBoot-capable can only take advantage of the file, Web, and Macintosh Management services of Mac OS X Server.

Question 8: How does a Macintosh start up from the network?

Answer: At startup, the NetBoot client computer broadcasts a BootP request on the network. BootP is a standard industry protocol for allowing computers to discover information about their network settings and the location of files to execute from a network server. The NetBoot server receives the BootP request and replies to the client's request with the information needed to start up. The client uses the information to configure its network settings and begins a TFTP download of the Mac OS into RAM. The client uses this file to finish booting.

Question 9: How do I set up a Macintosh to start up from the server?

Answer: A NetBoot-capable Macintosh requires no software setup to start up from the NetBoot server. To make a Macintosh boot the first time, hold down the N key until the Mac OS logo appears. After the computer is booted, simply set the Startup Disk Control Panel to start up from the network drive. From then on, the Macintosh will boot from the network without the aid of the N key.

Question 10: What version of the Mac OS runs on a NetBoot client?

Answer: NetBoot clients run Mac OS 8.5.1 with some minor modifications. These modifications allow the Macintosh to operate over the network and do not affect the user experience.

Mac OS X Server 1.x: Hardware and Compatibility FAQ

This article contains frequently asked questions about Mac OS X Server, with answers to those questions.

For more information on Mac OS X Server, please see articles:

Article 30604: "**Mac OS X Server: System Requirements**"
Article 60165: "**Mac OS X Server: General FAQ**"
Article 60166: "**Mac OS X Server: Operating System FAQ**"
Article 60167: "**Mac OS X Server: Services FAQ**"
Article 60168: "**Mac OS X Server: NetBoot/Macintosh Manager FAQ**"
Article 60170: "**Mac OS X Server: Pricing and Availability FAQ**"
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. What are the hardware requirements for Mac OS X Server?
2. To what extent does Mac OS X Server work with added third-party hardware?
3. Will Mac OS X Server be available for Intel-based computers?
4. Does Mac OS X Server 1.2 work with all the Power Macintosh G3 build-to-order options?
5. Does Mac OS X Server include RAID?

Question 1: What are the hardware requirements for Mac OS X Server?

Answer: The following computers work with Mac OS X Server 1.2.

- Power Mac G4 (AGP Graphics)
- Power Mac G4 (PCI Graphics)
- Macintosh G4 Server (except Gigabit Ethernet models)
- Power Macintosh G3
- Macintosh G3 Server
- Power Macintosh G3 All-In-One

Note: Mac OS X Server 1.2v3 supports the same computers as Mac OS X Server and adds support for the Power Mac G4 (Gigabit Ethernet).

For more information on Mac OS X Server hardware requirements, please see article 30604:
"**Mac OS X Server: System Requirements**"

Question 2: To what extent does Mac OS X Server work with added third-party hardware?

Answer: The extent to which Mac OS X Server will interoperate with third party hardware and software varies from one product to another. Consult with the developer of the hardware or software in question to determine its compatibility with Mac OS X Server. The Macintosh Products guide at: http://guide.apple.com/ provides a forum for developers to showcase their products. It is an excellent starting point for those searching for specific hardware or software solutions.

Question 3: Will Mac OS X Server be available for Intel-based computers?

Answer: Apple has no plans to provide Mac OS X Server for any architecture other than PowerPC.

Question 4: Does Mac OS X Server 1.2 work with all the Power Macintosh G3 build-to-order options?

Answer: No. It works with ATA and SCSI drives, Ethernet, and limited USB (for keyboard and mouse). It does not work with serial ports, FireWire, or LocalTalk.

Question 5: Does Mac OS X Server include RAID?

Answer: Mac OS X Server does not include RAID software. However, it is compatible with a number of Ultra2 SCSI-based RAID devices, including those from MicroNet.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: Pricing and Availability FAQ

This article contains frequently asked questions about Mac OS X Server versions 1.0 to1.2v3 only, with answers to those questions. Additional Mac OS X Server FAQs are listed at the bottom of this article.

Note: This software is no longer available as a retail shrinkwrap package. However, the hardware bundle is available in limited quantities through the Apple Store.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Questions answered in this article:

1. What is the price of Mac OS X Server?
2. What licensing do I get for that price?
3. What is included in the Macintosh Server G3 with Mac OS X Server configuration?
4. What build-to-order (BTO) options are available for the Macintosh Server G3 with Mac OS X Server?
5. Where will the software and hardware be available?
6. Will the products be available from Apple Enterprise Sales?
7. Are there any upgrade or volume discounts?

Question 1: What is the price of Mac OS X Server?

Answer: In the United States Mac OS X Server software is USD499 and is available to education customers for USD249. The hardware configuration, Macintosh Server G3 with Mac OS X Server, is USD4,999.

Question 2: What licensing do I get for that price?

Answer: Just about everything. You get unlimited client access (as much as your hardware can handle) for:

- Apache Web server
- Apple file services
- NetBoot network startup
- Macintosh Manager (both NetBoot and non-NetBoot systems)

For WebObjects, you get a basic 50-transaction-per-minute deployment license. You can purchase WebObjects upgrade licenses through the normal Apple Enterprise Software channels. For more information, see www.apple.com/webobjects.

Question 3: What is included in the Macintosh Server G3 with Mac OS X Server configuration?

Answer: The Macintosh Server G3 with Mac OS X Server includes a 400-MHz PowerPC G3 processor with 1MB of backside cache, 256MB of high-performance PC100 SDRAM, two 9GB 10,000-rpm Ultra2 LVD SCSI hard disk drives, built-in 10/100BASE-T Ethernet connector and four-port 10/100BASE-T Ethernet PCI card, CD-ROM drive, and Mac OS X Server software (preinstalled). This hardware configuration includes an unlimited-client license for Apple file services, NetBoot clients, and Macintosh Manager clients, and a 50-transaction-per-minute deployment license for WebObjects.

Question 4: What build-to-order (BTO) options are available for the Macintosh Server G3 with Mac OS X Server?

Answer: The Macintosh Server G3 with Mac OS X Server will offer the following BTO options:

- 256MB, 384MB, 512MB, 768MB, or 1GB of PC100 SDRAM
- Two or three 9GB 10,000-rpm Ultra2 LVD SCSI hard disk drives
- One, two, or three 36GB 7,200-rpm Ultra2 LVD SCSI hard disk drives
- Dual-channel Ultra2 LVD SCSI PCI card with any hard disk drive configuration
- Ultra SCSI PCI card
- Gigabit Ethernet PCI card
- LaCie external DDS-3 tape drive

For up-to-date information about options and availability, visit http://www.apple.com/store.

Question 5: Where will the software and hardware be available?

Answer: They will be available through most traditional Apple channels, including the online Apple Store, Apple sales agents, and most Apple resellers.

Question 6: Will the products be available from Apple Enterprise Sales?

Answer: Yes. For this release, Mac OS X Server will be the only vehicle for purchasing WebObjects 4 for Power Macintosh systems. WebObjects deployment licenses and consulting services will continue to be available solely through Apple Enterprise Sales.

Question 7: Are there any upgrade or volume discounts?

Answer: No. This is the first in a new line of server products.

Mac OS X Server 1.x: Setting up Anonymous FTP

I understand that I can configure my computer to allow guest (anonymous) access to my files using the File Transfer Protocol (FTP). How do I do this in Mac OS X Server?
This article has been archived and is no longer updated by Apple.
In order to set up anonymous FTP, first create a user named ftp in Network Manager. In the home directory, create the following directories:

```
bin
usr/lib
System/Library/Frameworks/System.framework/Versions/B
```

Copy the following files to their respective corresponding directories in the ftp directory:

```
/bin/ls
/usr/lib/dyld
/System/Library/Frameworks/System.framework/Versions/B/System
```

A complete directory listing is below. If dyld and the System framework are not copied, `ls` will not list any files.

```
dr-xr-xr-x  3 ftp  ftp  1024 Mar 18 04:36 System
dr-xr-xr-x  2 ftp  ftp  1024 Mar 18 04:22 bin
drwxr-xr-x  2 ftp  ftp  1024 Mar 18 04:42 pub
dr-xr-xr-x  3 ftp  ftp  1024 Mar 18 04:36 usr

./System:

Mac OS X Server 1.x: SMB and CIFS Support

Mac OS X Server does not come with support for SMB or CIFS.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001. Later versions of Mac OS X Server include SMB support.

Samba, which is freely available under the GNU public license, provides functionality with these protocols. For general information about Samba go to http://www.samba.org.

Samba for Mac OS X Server is availabe from:

http://www.peak.org/apple/macosx/server/Applications/Network/CLI/Samba/

This article provides information about a non-Apple product. Apple Computer, Inc. is not responsible for its content. Please contact the vendor for additional information.

Published Date: Feb 18, 2012

Mac OS X Server 1.x: Sometimes The Computer Restarts Itself During System Startup

Under certain circumstances a server computer running Mac OS X Server will automatically restart during system startup.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

After starting up into Mac OS 8 it is necessary to use the System Disk control panel to set Open Firmware to start up into Mac OS X Server. However, if the QuickTime Streaming Server, or if the AFP Server is enabled, the command that the System Disk control panel tells Open Firmware to use is not appropriate.

During system startup the operating system reads the `/etc/hostconfig` file and determines if either of these servers is on. If either server is set to "`YES`", "`srv = 1`" will be appended to the command in Open Firmware and the computer will restart. The computer must restart in order for the new command to take effect. This new command configures the kernel so that it will work properly with these servers.
Published Date: Feb 18, 2012

Mac OS X Server: What is nifind?

The nifind command is a utility for reading information from the NetInfo database to command line output.
This article has been archived and is no longer updated by Apple.
Using the NetInfo command line utilities requires knowledge of NetInfo and domains. Please see the following articles for more information

Article 60038: "**What is NetInfo?**"
Article 30832: "**A Basic Introduction to NetInfo Domains.**"

Nifind is a simple but powerful utility for finding and displaying information in NetInfo databases. It is useful for verifying in the existence of directories and for displaying their properties and values at the command line.

There are several options for using nifind

-a searches for the directory in the entire NetInfo hierarchy
-n causes the local domain not to be searched, useful if the local domain is not in question
-p prints the properties and values for a subdirectory
-t specify a timeout value in seconds. This may be needed in large NetInfo networks
-v verbose output mode, causes more information to be displayed

Examples

In these examples the network is a three level hierarchy. The top level is "/" the midlevel is "/scotland" and the local level is "/scotland/skye".

```
#nifind /machines
```

/machines found in /scotland/skye, id =1
/machines found in /scotland, id = 49
/machines found in /, id =190

This tells you that a `/machines` directory was found in all three domains, the local (skye), the mid-level (/scotland) and the root. It also displays the directory id number for each of these directories.

An example using the -p flag:

```
#nifind -p /machines/skye
```

/machines/skye found in /scotland, id = 321
name: skye
servers: skye/local
bootparams: root=aberdeen:/enterprise/release/private
bootfile: mach.rhap
ip_address: 192.168.156.1
en_address: 0:b:0:54:3b:5
owner: MacLeod

By specifying a subdirectory, you can display information on the properties in that directory and their values. This can be done for any of the directories in NetInfo. By default these are: aliases, fax_modems, groups, locations, machines, mounts, old_mounts, printers, services, and users. The subdirectories inside these default directories will vary with your setup.

Mac OS X Server: Where Should The Mac OS 8/9 Partition Be?

Where should the Mac OS 8/9 startup partition be?

This article has been archived and is no longer updated by Apple.

The Macintosh Extended Format (HFS+) partition that is used to start up Mac OS 8/9 should be first partition on the drive. The computer's ROM may have trouble finding this partition if it is not in this location and this may cause difficulty starting up into Mac OS 8 after Mac OS X Server is installed.

Mac OS X Server: Close View and NetBoot Clients Using the Panels Environment

When I use the CloseView control panel on a NetBoot client, the computer stops responding. What could be causing this?

This article has been archived and is no longer updated by Apple.

Close View control panel included with Mac OS 8.5.1 is not compatible with NetBoot clients in the Panels environment. Attempting to use this feature with panels will cause the NetBoot client to stop responding.

Published Date: Feb 18, 2012

Mac OS X Server: Keyboard Navigation Using Setup Assistant

When I use the keyboard to navigate the Setup Assistant, it doesn't always work. What's wrong?

This article has been archived and is no longer updated by Apple.

Using the keyboard (enter or tab keys) to advance or reverse panels in the Mac OS X Server Setup Assistant does not work on all screens. To ensure proper navigational behavior, always use the mouse to click the navigation buttons in the panels.

Published Date: Feb 18, 2012

Mac OS X Server: Support for 100 Percent Pure Java

Apple documentation says that Mac OS X Server is built on core technologies like "100 percent Pure Java" and includes "native support for 100 percent Pure Java (JDK 1.1.6)." However, Apple is not listed on the Sun Java compatibility list. Is Mac OS X Server "100 percent Pure Java" or not?

This article has been archived and is no longer updated by Apple.

Mac OS X Server includes a fully compatible Java VM (virtual machine) based on (JDK) Java Development Kit version 1.1.6. The Mac OS X Server Java VM supports applets that are "100 percent Pure Java." Applets (not VM's) must be tested to documented specifications to become certified as "100 percent Pure Java" compliant.

By supporting applets that are "100 percent Pure Java," Mac OS X Server is considered to be "100 percent Pure Java" compatible and compliant.

StuffIt Deluxe: Use Commercial Version for Important Work

I use StuffIt 1.5.1 to archive large amounts of data. I made one large StuffIt archive (about 20MB). Later, I extracted and deleted some of the files in the archive, making the size about 8MB. Then, I tried to extract more files, but got the following message: U-uh! The CRC-check for the resource fork has failed. Chances are that the file is trashed. Please use this file with caution. This happens when StuffIt has almost finished extracting the resource fork. That seems reasonable, because that is the time for calculating the CRC. Sometimes, I'll get the error messag above. Other times the machine bombs or just hangs. The message says that one should use the file with caution, but that is impossible, because StuffIt is unable to finish extracting the file. This happens with all the remaining files in the archive. I have tried to delete all files in the archive except one, but that does not help either. I suspect that the error is caused by a media fault. The drive in question is a Bernoulli Box from IOMega, and the error has occurred only on the two cartridges that came with the drive. Later, I ordered at least 30 cartridges from the USA without any problems.
This article has been archived and is no longer updated by Apple.
Sorry but we aren't familiar with StuffIt's error handling or bugs, nor are we familiar with this specific problem. The user might check with the programmer (name located on program's splash-screen) or the new distributor for any recovery routines they may have.

We generally caution users against using shareware software for critical work; you may wish to get the enhanced commercial StuffIt Deluxe. StuffIt Deluxe, a file compression, encryption, and file-archiving software. It is designed to compress files (or folders) of all types into compact spaces, potentially saving 50 to 75 percent of hard disk space. You can also password protection (DES algorithms) any archive. StuffIt Deluxe works on 512KE or larger Macintosh running System 5.0 or later.

For more details, search the Technical Info library under "Aladdin Systems" or "StuffIt Deluxe."

Mac OS Runtime for Java 2.1: Applet Security

Changing Java applet security settings in Microsoft Internet Explorer has no effect when using Mac OS Runtime for Java (MRJ).
This article has been archived and is no longer updated by Apple.
Microsoft Internet Explorer's applet security settings are intended for the Microsoft Java virtual machine, not Mac OS Runtime for Java (MRJ).

To change the settings for MRJ, use Apple Applet Runner, which is part of the MRJ 2.1 SDK. Apple Applet Runner has a user interface to change the properties file which controls the global security restrictions used in MRJ. To get to the properties dialog, select "Properties" from the "File" menu in Apple Applet Runner.

Apple Applet Runner is installed as part of MRJ 2.0 in the Apple Applet Folder in the Mac OS Runtime for Java folder in the Apple Extras folder. MRJ 2.1 does not install Apple Applet Runner. If Apple Applet Runner is missing, download the SDK from:

ftp://ftp.apple.com/developer/Development_Kits/MRJ_SDK_2.1.sit.hqx

Mac OS X Server: WebObjects Developer Disc Says "For Windows NT"

I have Mac OS X Server and the WebObjects Developer CD included in the package is labeled "For Windows NT." What version of WebObjects is on the disc?

This article has been archived and is no longer updated by Apple.

The WebObjects Developer CD included in the Mac OS X Server bundle is incorrectly labeled. The disc reads "For Windows NT," but the software on the disc is actually for the Mac OS X Server platform. There is a label on the disc's sleeve that points out this inaccuracy, but if the disc becomes separated from the sleeve there are two other ways to distinguish the Mac OS X Server CD from the Windows NT CD. Both discs include a version number and part number just below the words "For Windows NT" but the version and part numbers differ:

Version	Part Number
Mac OS X Server 4.0.1	Z691-2252-A
Windows NT 4.0	691-2093-A

Although the Mac OS X Server version of the software will install on Windows NT, entering the Mac OS X Server key results in a error message: "Invalid serial number for this platform."

Published Date: Feb 18, 2012

Mac OS 8: ObjectSupportLib Part of System File

What is ObjectSupportLib and when do I need it?
This article has been archived and is no longer updated by Apple.
ObjectSupportLib is a library developers use to implement the Open Scripting Architecture (OSA) object model. For example, how to refer to a word of a paragraph of a document.

As of Mac OS 8.0, the ObjectSupportLib extension is part of the System file. Although some applications may install it as a separate extension, it is not needed and can be safely removed without a loss of functionality.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: How to Remove the Software

I purchased Mac OS X Server and installed it on my computer. How can I remove it and reinstall Mac OS 8 that came with my computer?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

The Mac OS X Server installation guide recommended you partition your hard disk prior to installing Mac OS X Server. When Mac OS X Server was installed, the hard disk partition format was changed from Mac OS Standard format (also known as HFS) or Mac OS Extended format (also known as HFS Plus) to Mac OS X Server filesystem (also known as UFS). Mac OS 8 does not recognize UFS volumes. To fully ues the disk with the Mac OS that came with your computer, the hard disk will need to be reformatted.

Warning: Reformatting the hard disk will cause all data to be erased. Make sure any files you want to keep are backed up.

To reinstall the Mac OS that came with your computer do the following:

1. Backup any data files on the hard disk you wish to save.
2. Start up the computer with the Mac OS CD-ROM disc that came with your computer. (Insert the disc and press the C key on restart).
3. Run the Drive Setup utility (located on the CD) and reformat the drive Mac OS X Server is installed on. If the disk was partitioned all partitions will be reformatted.
4. Quit Drive Setup.
5. Run the Mac OS software installer on the CD-ROM disc.
6. Restart the computer.

Mac OS X Server 1.2: Print Manager and LPD

Mac OS X Server 1.2 cannot be used as a print spooler.
This article has been archived and is no longer updated by Apple.
LPD in Print Manager is not functional in Mac OS Server 1.2. However, AppleTalk based printers do work in the Print Manager environment for printing from the server.
Published Date: Feb 18, 2012

Mac OS X Server: Apple File Services Guest Accounts for AppleTalk Only Clients

Guest Access for AppleTalk only clients using Apple File Services does not work with this version of Mac OS X Server.
This article has been archived and is no longer updated by Apple.
If clients are capable of using an AppleShare client that work with TCP/IP, Guest Access operates correctly. All clients of the Apple File Service should use the AppleShare 3.8.2 client, which can drag installed from the CD-ROM disc. The client is found in the Utilities folder of the Mac OS X Server CD. The AppleShare 3.8.2 client is also installed on the Mac OS Extended format volume by the NetBoot Server installer.

Mac OS X Server: Navigating Fields In Mac OS X Server

Mac OS X Server has a number of anomalies relating to navigating fields in the interface.
This article has been archived and is no longer updated by Apple.
These anomalies are due to legacy code inherited from the various sources used to create Mac OS X Server. Some fields require the use of the enter, return, or tab keys after a value is entered to ensure that the value "sticks."

If you are having difficulty in this regard, try the combinations above after entering a value in a field.

Mac OS X Server: NetBooting, Apple File Services, and Mac OS Format Volumes

I've installed NetBoot on the Mac OS format volume, but it's not working. What could be wrong?

This article has been archived and is no longer updated by Apple.

Although the NetBoot Setup Assistant will allow installation of the software on Mac OS Standard format (HFS) volumes, NetBooting will not operate after the install is complete. NetBoot software must be installed on a Mac OS Extended format (HFS Plus) volume to operate properly. This is because Apple File Services will only share Mac OS Extended format volumes.

Mac OS X Server: Using RemoteAdmin With the Multiport Ethernet Card

Do I need to enable IP forwarding to use RemoteAdmin?
This article has been archived and is no longer updated by Apple.
To use RemoteAdmin on any segment of the network connected to a multiport Ethernet card, IP forwarding must be enabled on the server (available in the Control Panels' Network selection, Connections panel). If IP forwarding is not enabled, RemoteAdmin can be used by directing the browser to the IP address of the server port on the same segment as RemoteAdmin (no router or gateway is needed this way).

Mac OS X Server 1.x: Using WebAdmin with Internet Explorer

Internet Explorer keeps telling me that it's running out of memory when I run WebAdmin. How can I fix that?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

If you encounter a "running out of memory" condition using Internet Explorer to run WebAdmin, increase Internet Explorer's application memory size. To do this, locate and select the application's icon by clicking on it once. Choose Get Info from the File menu. Then select Memory from the Show popup menu. Increase the preferred size to at least 12000 K, then close the Get Info dialog box.
Published Date: Feb 18, 2012

Mac OS X Server 1.x: Compatible USB Devices

Not all Universal Serial Bus (USB) devices are compatible with Mac OS X Server.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Mac OS X Server comes with USB drivers for Apple USB keyboards and mouse devices only. Using multiple or third-party keyboards and mouse devices will not work with this version of Mac OS X Server.

Mac OS 8.6: System Requirements

What are the system requirements for Mac OS 8.6?
This article has been archived and is no longer updated by Apple.
To install Mac OS 8.6, your computer must have:

- One of the following Mac OS-based Apple computers with a PowerPC processor:
- iMac
- Power Macintosh G3
- Power Macintosh G3 (Blue and White)
- Any Power Macintosh, PowerBook, or Workgroup Server computer with a 4-digit model number.
    - Mac OS 8.6 may not function with a Mac OS 8.6 compatible Apple Power Macintosh computer that has been upgraded with a non-Apple processor upgrade card. Please check with the card's manufacturer for compatibility information.
    - Computers upgraded with Apple's Power Macintosh 233-MHz Processor Upgrade Kit are supported.
    - The Power Macintosh Upgrade Card (supported in the Quadra 700), the Macintosh Processor Upgrade (supported in the 575), and all 680X0 processors are NOT supported with Mac OS 8.6.
- 190 MB to 250 MB free disk space (full install of Mac OS 8.5 and Mac OS 8.6 Update), or 50 MB free disk space when only updating with Mac OS 8.6 Update.
- at least 24 megabytes (MB) of random-access memory (RAM) installed; 32 MB is recommended

Note: You cannot use Mac OS 8.6 if your computer has been upgraded with a PowerPC processor card but still has a 68040 (or earlier) processor that is accessed during startup.

If your computer has less than 32 MB of built-in RAM, you must use virtual memory. (Virtual memory is turned on automatically after installation).

If you don't know how much RAM your computer has, open the Apple menu and choose About This Computer (or About This Macintosh). Look at the number next to Built-in Memory.

To install the recommended software, you need at least 190 MB of free space on your hard disk. To install the optional components, you need sufficient storage space on your hard disk. The exact amount of space needed varies for different computer models, hard disk sizes, and the optional software you choose to install. The Installer will display a message if you do not have enough free space to install the software you select.

Many application programs use your hard disk to temporarily store information. For best performance, keep at least 10 percent of your disk space free. To determine the amount of free space on your hard disk after you've installed the Mac OS, select the hard disk icon on your desktop, then open the File menu and choose Get Info. Look at the number next to the word "Available."

Mac OS X Server: Third-Party PCI Cards Require Drivers

Can I use a third-party PCI card with Mac OS X Server?

This article has been archived and is no longer updated by Apple.

Mac OS X Server uses a different driver model than Mac OS 8/9. Third party PCI card vendors must write drivers specifically to support Mac OS X Server. Mac OS X Server only includes drivers to support Apple's specific SCSI and Ethernet cards for the Power Macintosh G3 or Power Mac G4 lines. Due to variations between Apple and third party cards, even third-party cards that are very similar to the Apple-supplied cards may not function properly, if at all. Contact your card's vendor to determine if they sell a version of their product that they believe will work with Mac OS X Server.

Mac OS X Server 1.x: Mac OS Extended Format Volumes Do Not Work With NFS Export

Should I export Mac OS Extended format volumes as NFS mount points?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Under Mac OS X Server it is possible to export any Mac OS Extended format (HFS Plus) volume as an NFS mount point. However, please be aware that the NFS is based on the Unix-style UFS file system which is case-sensitive and no resource fork information is available under an HFS Plus volume mounted through NFS. This is to the filesystem data structure difference between NFS and HFS Plus.

Because of this, Apple does not recommend or support exporting Mac OS Extended volume as an NFS mount point in the current version of Mac OS X Server. (This is not an issue in Mac OS X Server 10.0.3 and later).

Power Macintosh G3 (Blue and White): Rage 128 Video Memory Usage

This article describes how the video memory on the Rage 128 video card that ships with some Power Macintosh G3 (Blue and White) computers is allocated for2D and 3D operations.
This article has been archived and is no longer updated by Apple.
The Rage 128 card doesn't have a fixed amount of memory assigned to either 2D or 3D operations. The 16 MB of memory is assigned dynamically, as needed for either operation, meaning that any memory not used for your 2D operations will be made available for 3D operations.

Note: This information doesn't apply to other ATI-based chipsets, such as the Rage II, Rage IIc, or Rage Pro used in some other Apple products.

Mac OS X Server 1.x: Choosing the Startup OS Using System Disk Application

I have Mac OS X Server and Mac OS 8.x or Mac OS 9 installed on my Power Macintosh G3 or Power Mac G4. I want to be able to start up from either operating system (OS). Is this possible?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Mac OS X Server and Mac OS 8.x or Mac OS 9 can be installed on the same computer, and you can choose the OS you want to use to start the computer.

Most Power Macintosh computers (and iMacs) load a small program called Open Firmware when they are first turned on. Open Firmware determines where the computer's startup device is (such as a disk) and which file on that device is used to start up the computer (such as Mac OS 8).

Some of the settings used by Open Firmware can be changed using a utility program that runs in OS 8.x and OS 9 called System Disk. It is located on the Mac OS Extended format (HFS Plus) partition of the Mac OS X Server CD-ROM disc in the Utilities folder.
Note: You cannot select a Mac OS X Server disk as your startup disk in the Startup Disk Control Panels in Mac OS 8.x or OS 9.

The System Disk application contains an icon list of disk partitions available to the computer labeled with the kinds of operating systems installed on each partition. At a minimum, the System Disk application will contain options for "Open Firmware" and "Mac OS" on the computer's hard disk. If the Mac OS X Server CD-ROM disc in the drive, you'll also see the partitions and versions of system software available on the disc. Additional partitions may also be listed if you have attached additional storage devices to the computer.

In the System Disk window, Mac OS and Mac OS Extended format partitions appear with a Mac OS badge on their icons, and Mac OS X Server partitions appear with an "X" badge on their icons.

To select the startup OS and disk, follow these steps:

1. Open the System Disk application. This program is provided on the Mac OS X Server disc within the Utilities folder.
2. In the list of devices, select the volume that will start up the computer.
3. Click Save and quit the application.
4. Restart the computer.

The computer will now start up from the volume that you selected.

Using the System Disk utility program in this way, you can easily switch between the two operating systems.

If you expect to frequently switch between systems, you may want to install the Mac OS 8 System Disk extension (located in the same folder as the System Disk utility program on the Mac OS X Server disc). When this extension is installed, holding down the Option key during startup opens the System Disk utility program and allows you to choose the partition and OS you want to use.

If Mac OS X Server is set as the computer's default OS in Open Firmware, holding down the Option key until the Happy Mac icon appears stops the computer from starting up with Mac OS X Server, and makes the computer start up with Mac OS 8 by default (if Mac OS 8.x or Mac OS 9 is installed on an available partition). Holding down the Option key longer than this during startup will open the System Disk utility as described above.

Resetting the Parameter RAM (PRAM) (Option-Command-P-R) at startup is another way to reset Open Firmware's settings to start up with Mac OS 8 or Mac OS 9.

For instructions on formatting a hard disk for use with both operating systems, see article 60175: "**Where Should the Mac OS 8 Partition Be Located?**"

If you have OS X Server and Mac OS 8.6 or Mac OS 9 installed on a Power Mac G4 or a Macintosh Server G4, you can also select the OS and disk from which the computer will start up using the Startup Manager. For instructions on how to use the Startup Manager, see article 106178: "**Startup Manager: How to Select a Startup Volume**"

Mac OS 8.6: Error Installing With Norton Crashguard Enabled

When I am installing Mac OS 8.6 Norton Crashguard says the Mac OS installer caused the computer to crash then attempts to save it from doing so. The computer then becomes unresponsive and I can't force quit, I can only restart. How can I fix this?
This article has been archived and is no longer updated by Apple.
Simply turning Norton Crashguard off will prevent this error from happening. The Mac OS Installer quits all running applications as a normal part of the installation process. Norton Crashguard incorrectly interprets this action as a crash.

You should install Mac OS 8.6 by starting up with extensions off. You do this by holding down the Shift key when you turn the Macintosh on. You could also disable non-Apple extensions using the Extensions Manager (in the Control Panels folder). If you have a Mac OS 8.6 CD-ROM disc, you should start up your Macintosh from the disc to install the OS.

Mac OS X Server: Video Acceleration Supported for ATI Cards

Does Mac OS X Server use video acceleration?
This article has been archived and is no longer updated by Apple.
Mac OS X Server does use video acceleration for the Built-In ATI video as well an any ATI Build To Order video cards.

MacOS.app does not use hardware video acceleration.
Published Date: Feb 18, 2012

Final Cut Pro 1.0: System Requirements

This article outlines the system requirements for Final Cut Pro 1.0
This article has been archived and is no longer updated by Apple.

- A Power Macintosh G3/266 computer (G3/300 or faster required for DV)
- Mac OS 8.5 or later
- 128 MB of RAM
- A CD-ROM drive
- A 6 GB, A/V (Audio/Video rated) drive (16 GB recommended)
- A true-color display
- ATI built-in video support on G3 models (required for DV)
- An Apple FireWire or other QuickTime-compatible digital video card for capturing videofrom an external source or exporting video to tape
- The correct FireWire or device control cable and any additional cables you may need for connecting your deck or camcorder to your computer

Note: Final Cut Pro 1.0 is not supported on iMac, Power Mac G4 or PowerBook products.

Mac OS 8.6: What‘s New - Expanded Sherlock Capabilities

This article describes the new features of Mac OS 8.6.
This article has been archived and is no longer updated by Apple.

Searching the Internet

Sherlock has improved the ability to search behind firewalls, including SOCKS and authenticated proxy servers. You can also set the number of Internet connections that you can make simultaneously in Sherlock's Preferences window.

The Search Internet panel is now resizeable so you can easily see all available search sites. Click the new Uncheck All button to quickly deselect the selected search sites.

Find by Content

The "Find by Content" section of Sherlock now allows you to index and search PDF and HTML files. You can also index or search items with a particular label, or index an individual folder.

You index a folder using the Contextual menu (press the Control key and click a folder). This is particularly useful when you perform frequent indexes of volumes where few folders change. If the contents of an individual folder have changed, you can update the index for just the changed folder.

Published Date: Feb 18, 2012

Mac OS 8.6: What‘s New - Improved Media Integration

This article discusses the new features of Mac OS 8.6.
This article has been archived and is no longer updated by Apple.

ColorSync 2.6

The ColorSync control panel is newly designed and provides additional file format support for JPEG and GIF. The file format plug-in framework performs critical color operations, such as simulation and proofing of common formats used for the Internet and publishing.

ColorSync 2.6 also affords flexible workflow combinations. The 18 new AppleScript commands that come with ColorSync provide a complete automated solution for publishing. Additional software includes more profiles and CMMs for expanded color publishing workflow.

Monitors & Sound

Use Apple's monitor calibrator in Color section of the Monitors & Sound control panel to make it easier to view and customize color settings.

Surfing the Web is better than ever

Mac OS Runtime for Java (MRJ) 2.1.1 offers performance improvements in both speed and stability. MRJ now supports a wider selection of Java applets and applications. MRJ is based upon Java Development Kit (JDK) 1.1.7, from Sun Microsystems.

Mac OS 8.6: What‘s New - Greater Device Access and Capabilities

This article describes new features in Mac OS 8.6.
This article has been archived and is no longer updated by Apple.

Games support

Playing your favorite games is easier than ever. Game Sprockets are now integrated into the Mac OS.

Support for USB and FireWire devices

Now you can connect USB keyboards, mice, or other pointing devices to USB-capable computers. You can also connect USB printers and mass storage devices.

Connect any FireWire device to a FireWire-capable computer to enjoy a super high-speed transfer rate. FireWire makes it easy to download large files, such as digital video, from any FireWire-capable device.

Mac OS 8.6: What's New - Improved Printing and Font Management

This article describes new features of Mac OS 8.6.
This article has been archived and is no longer updated by Apple.
Mac OS 8.6 includes LaserWriter 8 version 8.6.5 which adds support for printing to USB-compatible PostScript printers. LaserWriter 8.6.5 provides support for PostScript printers that have USB ports built-in, and those that have IEEE 1284 parallel compatible ports. IEEE 1284 compliant printers may be connected to your Macintosh via a USB-to-Parallel adapter cable.

Secure printing and font management
Enjoy secure printing using AppleShare IP 6.1 or later and the new LaserWriter 8.6.5 driver. LaserWriter 8.6.5 also allows you to connect USB PostScript printers to your computer.

In the new LaserWriter 8.6.5 print dialog box, you can create a Job/Font log to view a history of your printing jobs and fonts used. You can also choose TrueType over Type 1 fonts, and force all fonts to be downloaded to the printer.

PostScript printer support
The new Desktop Printer Utility 1.2 allows you to create desktop printers for PostScript printers that are connected to your computer using USB or LPR (TCP/IP).

Published Date: Feb 18, 2012

Using DVD-RAM discs

Learn how to use and initialize DVD-RAM discs.
This article has been archived and is no longer updated by Apple.

Using DVD-RAM Discs

DVD-RAM discs can be used with Macintosh computers that have a DVD-RAM drive, or with certain Generation 3 DVD-ROM drives. These computers should also have this software installed:

- Mac OS 8.6 or later
- Apple CD/DVD Driver system extension
- Foreign File Access system extension
- UDF Volume Access system extension

DVD-RAM disks can be used to store information, as with any hard disk, floppy disk, or other removable, recordable media.

Apple DVD-RAM drives work with Mac OS X. You can use and burn DVD-RAM discs. However, you can't burn CD-RW or DVD-R discs with an Apple DVD-RAM drive in Mac OS X.

Formatting

DVD-RAM discs can be initialized using the Universal Disk Format (UDF), Mac OS Standard, Mac OS Extended, or DOS formats. The UDF format allows you to share information with any computer platform that works with UDF 1.5.

Choosing Erase Disk from the Mac OS 9 or earlier Special menu in the Finder also initializes a DVD-RAM disc. For Mac OS X, use Disk Utility.

Starting Up From DVD-RAM Media

Beginning with Mac OS 9.0.4, Power Mac G4 (AGP Graphics and Gigabit Ethernet) computers can use DVD-RAM media as a startup disk. Other computers, which may have a DVD-RAM drive, including the Power Macintosh G3 (Blue and White) and the Power Mac G4 (PCI Graphics) cannot use DVD-RAM discs as a startup disk.

Follow these instructions to start up from a DVD-RAM disc:

Power Mac G4 (AGP Graphics)

1. Use Drive Setup 1.9.2 or later to format the DVD-RAM media.

2. Install Mac OS 9 and the Mac OS 9.0.4 Update on the DVD-RAM disc. If your computer is running Mac OS 9.0.4 or later, you may drag copy that System Folder to the DVD-RAM media.

Power Mac G4 (Gigabit Ethernet)

1. Use Drive Setup 2.0.1 or later to format the DVD-RAM media.

2. Install Mac OS from the Restore or Install CD that came with your computer onto the DVD-RAM disc, or drag copy the active System Folder from your hard disk.

The DVD-RAM disc can now be used to start up a Power Mac G4 (AGP Graphics) computer after either:

- using the Startup Disk control panel to select the DVD-RAM disc as the startup disk.

- using the Startup Manager by holding down the Option key at system startup time

- pressing and holding down the C key at system startup time

DVD-ROM Drives

Most Generation 3 (or higher) DVD-ROM drives can read Type 2 DVD-RAM discs if they are removed from their cartridge. (See the DVD-RAM disc's packaging for instructions on how to remove the disc from its cartridge.)

DVD-ROM drives use only one side of a DVD-RAM disc. If you are using a double-sided DVD-RAM disc, you must eject the disc and flip it over to use the other side.

CD-R discs

DVD-RAM drives can read CD-R and CD-RW discs, but cannot record them.

Published Date: Feb 18, 2012

Mac OS X Server: MacOS.app and Mac OS X Server Performance

MacOS.app is a high-performance virtual Mac OS within a Mac OS X Server application, but isn't intended to be used while the server is online.
This article has been archived and is no longer updated by Apple.
MacOS.app, the Macintosh-compatibility application provided with Mac OS X Server, is a complete and robust implementation of a virtual machine within a BSD application program. It uses a real Macintosh ROM image, loads and executes full, genuine Mac OS code (and can even start its virtual self from an unaltered, attached Mac OS 8.5 startup disk). It runs virtually any properly written Mac OS application within its own environment. (See also article 30607, "**Mac OS X Server: What Is MacOS.app?**").

To accomplish all this, MacOS.app uses many system resources. Running MacOS.app while Mac OS X Server is offering services from the underlying BSD/Mach operating system will have a negative effect on the smoothness and performance levels of those services. Actually running application programs within the MacOS.app will have a greater negative effect.

MacOS.app is provided with Mac OS X Server as an administrative convenience, and as a demonstration of the ongoing evolution of Mac OS X and Mac OS. At times when the server is not online, it is a very functional Mac OS workstation. It should not, however, be used to implement additional services. Specifically, Mac OS-based server services should not be run on a Mac OS X Server system that is online with connected clients. This includes database services, mail or group calendaring services, and Mac OS-based backup or archiving systems. When native Cocoa- or Carbon-based API versions of these packages are released by their respective developers, they can run on the Mach/BSD Mac OS X Server side and offer the performance and reliability benefits for which this operating system was developed.

Mac OS X Server's Mach kernel/BSD OS offers the server benefits of Unix-derived operating systems such as fine-grained preemptive multitasking, high-performance virtual memory, smoothly asynchronous I/O for a large number of connected users, robust security, and high reliability.

Mac OS X Server: Only OS Installer Disc Appears On Desktop of Mac OS 8

My Mac OS X Server disc appears on the desktop in Mac OS 8, but whenever I insert any of the three other discs that came with Mac OS X Server while in Mac OS 8, the computer reports that the disk is unreadable.

This article has been archived and is no longer updated by Apple.

Of the four discs that come in the Mac OS X Server package, only one will appear on the desktop in Mac OS 8. This is the main install disc. It appears because it has both a Mac OS Extended format (HFS Plus) partition and a UFS format partition on it. The other three discs contain only UFS partitions and will only be available while in Mac OS X Server.

```
Mac OS X Server disc  (contains both UFS and HFS Plus partition)
NetBoot disc          (contains only UFS partition)
WebObjects disc       (contains only UFS partition)
Solutions disc        (contains only UFS partition)
```

Mac OS X Server 1.x: Using Macintosh Management Server Without NetBoot

Can I create a Macintosh Management Server with out the NetBoot process? I want to control access to non-NetBoot Macs without having any NetBoot clients on the network.

This article has been archived and is no longer updated by Apple.

You can control access to non-NetBoot computers without having NetBoot clients by following these steps:

1. Install the NetBoot software and open the NetBoot Setup Assistant.
   - Reply Yes to configuring the server as a Macintosh Management Server.
   - Provide valid IP numbers for NetBoot clients. It can be a range or one IP number.
   - On the last screen of the Setup Assistant, click the Quit button (not the Restart button).
2. Select Computer Settings, Network from the Apple Menu.
   - Click the Connections tab.
   - Select BootP from the Show pop-up menu.
   - Click Global BootP to select it.
   - Select Off in the Global Bootp Settings panel.
   - Quit the Network applcation.
3. Restart your server for all changes to take effect.

If you decide later to add some NetBoot clients you can run the NetBoot Setup Assistant to configure it as a NetBoot server.

Mac OS: Inserting Jaz Cartridge Causes OS to Ask For Reinsert

Inserting a Jaz cartridge may cause a dialog to appear asking to "insert <Jaz cartridge>" again.
This article has been archived and is no longer updated by Apple.
This appears to be an issue with earlier versions of the Iomega driver. Mac OS 8.5 and later install a newer version that should prevent this dialog. Iomega Tools has an option to update any older driver on a cartridge with the current one when inserted. Therefore, you may experience the dialog the first time you insert a cartridge under Mac OS 8.5 before the driver is updated. Subsequent uses of the cartridge should not cause the dialog to appear.

To bypass the dialog, type command-period.

Apple Video Player: No Video At Certain Bit Depths

On my 6500, when I launch Apple Video Player I notice that I don't get any video unless I switch to 256 colors (as opposed to Thousands or Millions of colors). What's wrong?

This article has been archived and is no longer updated by Apple.

There is an issue with the video digitizer of the 6500, 5500, and Twentieth Anniversary Macintosh which can cause this to happen. The issue is fixed in Apple Video Player 1.7.3 that Apple plans to include with the next system update. Until then, continue to switch to 256 colors if necessary.

Apple Network Server 500,700: Open Firmware Read Me

This article contains a comprehensive overview of Apple's implementation of PCI Open Firmware on the Apple Network Servers 500 and 700. While it is a reference specific to that particular product line, Open Firmware is an industry cross-platform standard, and most of the information included applies broadly to all PCI Macintosh systems.
This article has been archived and is no longer updated by Apple.
About Open Firmware for the Network Server

Contents

* Introduction
* Starting Up Open Firmware
* Using Open Firmware
* Open Firmware Command Summary

Introduction

Open Firmware provides features that enable you to access low-level information about your Network Server. Using Open Firmware, for example, you may examine settings stored in the server's non volatile memory (NVRAM).

Open Firmware is a standard software architecture for controlling a computer before the operating system begins execution. The complete specification for the Open Firmware standard is defined in the IEEE standard document IEEE P1275-1994 Standard for Boot Firmware. The Open Firmware software orchestrates how the hardware loads the operating system and defines which properties (or features) of the hardware are available for use by the operating system. The Open Firmware command language is based on Forth.

For the latest version of Open Firmware software and documentation, click the Network Server button at the World Wide Web site http:/www.solutions.apple.com. [**Note**: this service and web site are no longer available].

Starting Up Open Firmware

To start up Open Firmware, hold down these keys while the server is restarting:

Command-Option-O-F

Enter Open Firmware commands at the `>ok` prompt. Separate each command by one or more spaces. A summary of general commands available in this implementation of the IEEE standard is provided at the end of this section.

Using Open Firmware

These commands provide low-level information about your Network Server:

`printenv`
Displays configuration settings stored in NVRAM. For example, one configuration setting specifies the boot path for the operating system. This setting is named boot-device. There is also a setting named diag-device which identifies the boot path for loading diagnostics when the server key switch is in the left (service) position.

The configuration setting name appears in the left column, the current setting appears in the middle column, and the default setting is in the right column. Use the set-default command to restore default settings when appropriate. If you encounter difficulties starting up the Network Server operating system, try setting defaults. Also, you should copy down the current settings after you install the operating system. If you later experience problems starting up the operating system, you can use printenv to check the settings using this command to determine verify the configuration settings.

`devalias`
Displays name aliases to devices stored as properties in the device tree. A name alias is an abbreviated way of referring to a device path name. For example, to boot the Network Server Diagnostic Utility, you specify the name alias for the floppy drive, `fd:`

```
boot fd:diags
```

`probe-scsi1`
Searches the Fast and Wide SCSI bus 0 and for each device attached displays the SCSI ID, the type of device, and other pertinent information such as the device's firmware version number. Use this command to verify that the devices in the top four drive trays are correctly recognized by the Network Server.

`probe-scsi2`

Searches the Fast and Wide SCSI bus 1 and for each device attached displays the SCSI ID, the type of device, and other pertinent information such as the device's firmware version number. Use this command to verify that the devices in the bottom four drive trays and the two rear bracket-mounted internal drives (Network Server 700 only) are correctly recognized by the Network Server.

`dump-device-tree`
Displays the device tree, which lists all features and devices in the Network Server encoded into a specific data format. Use the spacebar to control scrolling of the list.

The following command are used to change configuration settings stored in NVRAM. The *name-alias* variable is the setting name. The *value* variable can be a number, logical name (true, false), or a sequence of text.

`setenv` *name-alias value*
Use this command to change the specified configuration setting to the indicated value. For example, to change the OS boot device:

```
setenv boot-device disk3:aix
```

This adds disk 6 to the boot search path:

```
setenv diag-device cd disk6 fd:diags
```

`set-default` *name-alias*
This command restores the default of the named configuration setting. This example restores the boot device setting to `disk2:aix:`

```
set-default boot-device
```

This command restores the default diagnostic device to `disk2:aix:`

```
set-default diag-device
```

`set-defaults`
Restores the factory defaults for all the configuration settings.

Configuration Settings to Check in Case of Problems

If you encounter problems when the operating system starts up, check these configuration settings:

`auto-boot?`
Must be true in order to enable automatic booting of the operating system or the diagnostics when the key switch is the in the service position.

`load-base`
The Network Server Diagnostic Utility expects this number to be 4000 or greater.

`diag-device`
In order to be able to boot the Network Server Diagnostic Utility from the floppy drive, the value of `diag-device` must include `fd:diags`. Any device preceding `fd:diags` must be unmounted or removed. For example, the default setting for `diag-device` is `cd fd:diags`. This means that the search order for a bootable device begins with the CD-ROM drive and proceeds to the floppy drive only if the CD-ROM drive does not contain a bootable CD. You must remove the CD-ROM disk in this case in order to boot the floppy drive.

`boot-device`
The factory default for booting the operating system is disk2 or the hard drive contained in drive tray three (Fast and Wide bus 0 SCSI ID 2). If this value becomes corrupt or changes, the AIX operating system won't boot. If you are unable to restore this setting to the default or you cannot change the setting with the `setenv boot-device` command, then you may still be able to boot AIX by manually entering the boot command:
`boot disk2:aix`

Open Firmware Command Summary

Changing the Number Base & Number Input/Output Commands

Command	Stack	Comment
decimal	(--)	Set the number base to 10.
d# number	(-- n)	Interpret the next number in decimal.
hex	(--)	Set the number base to 16.
h# number	(-- n)	Interpret the next number in hex.
u.	(n --)	Display the unsigned number.

.d	(n --)	Display n in decimal without changing number base system.
.h	(n --)	Display n in hex without changing base.
.	(n --)	Display a number in the Current base.
.s	(--)	Display contents of data stack.

Memory Access Commands

Command	Stack	Comment
!	(n adr16 --)	Store a 32-bit Number at adr16, 16-bit aligned.
@	(adr16 -- n)	Fetch a 32-bit Number from adr16.
c!	(n adr --)	Store low byte of n at adr.
c@	(adr -- n)	Fetch a byte from adr.
cpeek	(adr -- [byte] ok?)	Fetch the byte at adr. Return the data and true if the read access was successful. Return false if an error occurred.
cpoke	(byte adr -- ok?)	Store the byte to adr. Return true if the write access was successful. Return false if an error occurred.
comp	(adr1 adr2 len -- n)	Compare two byte arrays, n=0 if arrays are identical, n=1 if first byte that is different is greater in array#1, n= -1 otherwise.
dump	(adr len --)	Display len bytes of memory from adr.
fill	(adr size byte --)	set size bytes of memory to byte.
l!	(n adr32 --)	Store a 32-bit number at adr32, 32-bit aligned.
l@	(adr32 -- n)	Fetch a 32-bit number from adr32.
lpeek	(adr -- [long] ok?)	Like cpeek, but 32-bit access.
lpoke	(long adr -- ok?)	Like cpoke, but 32-bit access.
move	(adr1 adr2 n --)	Copy n bytes from adr1 to adr2.
w!	(n adr16 --)	Store a 16-bit number at adr16.
w@	(adr16 -- n)	Fetch a 16-bit number from adr16.
wpeek	(adr -- [word] ok?)	Like cpeek, but 16-bit access.
wpoke	(word adr -- ok?)	Like cpoke, but 16-bit access.

Memory Mapping Commands

Command	Stack	Comment
do-map	(phys virt size mode --)	Map a region of 32-bit physical address at phys to a region of 32-bit virtual address at virt, the mode is 0 for Memory and 0x28 for input/output normally. Open Firmware turns on MMU translation and uses virtual address for Memory
do-unmap	(virt size --)	Unmap the previous mapped region.

PCI Registers Access Commands

Command	Stack	Comment
rb!	(n adr --)	Store low byte of n at adr.
rb@	(adr -- n)	Fetch a byte from adr.
rl!	(n adr32 --)	Store a 32-bit number at adr32, 32-bit aligned.

rl@	(adr32 -- n)	Fetch a 32-bit number from adr32.
rw!	(n adr16 --)	Store a 16-bit number at adr16.
rw@	(adr16 -- n)	Fetch a 16-bit number from adr16.
Note: For big endian registers use xb!, xb@, xl!, xl@, rw!, rw@ instead. If the (big endian) register access doesn't require special instruction such as eieio, it may use c!, c@, l!, l!, w!, w@.		

Stack Manipulation Commands

Command	Stack	Comment
bounds	(start-adr size -- end-adr start-adr)	This is equal to:over + swap
2drop	(n1 n2 --)	Remove two items from the stack.
2dup	(n1 n2 -- n1 n2 n1 n2)	Duplicate two items.
clear	(??? --)	Empty the stack.
drop	(n --)	Remove one item from the stack.
dup	(n -- n n)	Duplicate the top stack item.
over	(n1 n2 -- n1 n2 n1)	Copy the second item to the top.
rot	(n1 n2 n3 -- n2 n3 n1)	Rotate three stack items.
swap	(n1 n2 -- n2 n1)	Exchange the top two items.

Arithmetic Commands

Command	Stack	Comment
*	(n1 n2 -- n3)	Multiply n1 * n2
+	(n1 n2 -- n3)	Add n1 + n2
-	(n1 n2 -- n3)	Subtract n1 - n2
/	(n1 n2 -- n3)	Divide n1 / n2 (truncated)
<<	(n1 n2 -- n3)	Left shift n1 by n2 bits
>>	(n1 n2 -- n3)	Right shift n1 by n2 bits
and	(n1 n2 -- n3)	Bitwise logical and
mod	(n1 n2 -- n3)	Remainder of n1 / n2
not	(n1 -- n2)	Bitwise logical inversion
or	(n1 n2 -- n3)	Bitwise logical or
xor	(n1 n2 -- n3)	Bitwise logical exclusive or.

Examining and Creating Device Aliases

devalias	Display all current device aliases.
devalias <alias>	Display the device path name corresponding to <alias>.
devalias <alias> <device-pathname>	Define an <alias> representing the <device-pathname>.

Device Tree Browsing Commands

dump-device-tree	Dump the whole system device tree.
.properties	Display the names and values of the current device node's properties.
dev <device-pathname>	Select the indicated device node, making it the current node.
dev <node-name>	Search for a node with given name in the subtree below the current node, and choose the first such node found.
dev ..	Choose the device node that is the parent of the current node.
dev /	Choose the root machine node.
show-devs <device-pathname>	Display all the devices directly beneath the given device. For example, show-devs /bandit

device-end	Leave no node selected.
ls	Display children of the current node.
pwd	Display the current device path name.
words	Display the names of the current node's methods.
select-dev (str,len --)	Select the desired device node in order to execute the device methods under it. This requires all nodes of the desired device path have open method.
unselect-dev	Unselect the previous selected device node.

If-then-else Commands

else (--)	Execute the following code if 'if' failed.
if (flag --)	Execute the following code if flag is true.
then (--)	Terminate if ... then ... else.

Begin (conditional) Loop Commands

again (--)	End a begin ... again infinite loop.
begin (--)	Begin a begin ... while ... repeat, begin ... until, or begin ... again loop.
repeat (--)	End a begin ... while ... repeat loop.
until (flag --)	Continue executing a begin ... until loop until flag is true.
while (flag --)	Executing a begin ... while ... repeat loop while flag is true.

Do (Counted) Loop Commands

+loop (n --)	End a do ... +loop construct; add n to loop index and return to do (if n < 0, index goes from start to end inclusive).
do (end start --)	Begin a do ... loop. Index goes from start to end-1 inclusive. Example: 10 0 do i . loop
i (-- n)	Loop index.
j (-- n)	Loop index for next enclosing loop.
leave (--)	Exit from do ... loop.
loop (--)	End of do ... loop.

Comparison Commands

<	(n1 n2 -- flag)	True if n1 < n2.
<=	(n1 n2 -- flag)	True if n1 <= n2.
<>	(n1 n2 -- flag)	True if n1 <> n2.
=	(n1 n2 -- flag)	True if n1 = n2.
>	(n1 n2 -- flag)	True if n1 > n2.

Controlling Text Input Commands & Display Text Output Commands

ascii <c>(-- n)
Get numerical value of first ASCIIcharacter of next word.

key (-- char)
Read a character from the assigned input device's keyboard.

key? (-- flag)
True if a key has been typed on the input device's keyboard.

cr (--)
Go to the next line on the display.

File Loading Commands

boot [specifiers]

```
Boot file from specified source.

dl
Load a Forth file over a serial line.

init-program
Initialize to execute a binary file.

load [specifiers]
Load data from specified device.

NOTE: Use boot (or load) one of these four ways:

(1) boot
(2) boot <device-specifier>
(3) boot <arguments>
(4) boot <device-specifier> <arguments>

NOTE: When using the floppy drive (name-alias is fd), the disk must be high density 1.4 MB formatted for the
MacOS or DOS environments.

(1) For a MacOS floppy, <device-specifier> is fd:<filename>
(2) For a DOS floppy, <device-specifier> is  fd:,<filename>
```

Defining Words

```
: <name>( -- )      Start creating a new command word.
;   ( -- )          Finish creating the new word.
```

Manipulating Text Strings

```
" <string>"( -- adr len )   Collect an input string.
```

Redirecting I/O

```
input   (device-str -- )
Select the indicated device for console input, device may be a device name-alias.

io  (device-str -- )
Select device for subsequent input and output. Eg.  ttyb:9600

output  (device-str -- )
Select the indicated device for console output. Eg.  screen output
```

Emergency Keyboard Commands

```
NOTE: Hold down keys during Open Firmware power on sequence.

Command-Option-O-F  Abort auto booting if auto-boot? is true.
Command-Option-P-R  Reset NVRAM contents to default values.
```

Miscellaneous Operation Commands

```
eject [fd]
Eject the floppy disk from the drive.

get-msecs ( -- ms )
Return the approximate current time in milliseconds.

ms ( n -- )
Delay for n milliseconds. Resolution is 1 millisecond.

reset-all
Reset the entire system (similar to a power cycle).
```

PowerPC Register Commands

%r0 through %r31	(-- value)	Return saved copy of the given register.
%srr0 & %srr	(-- value)	Return saved copy of Save/Restore reg.
%sprg0 through %sprg3	(-- value)	Access saved copies of SPRG registers.
%cr	(-- value)	Return saved copy of Condition Register.
%ctr	(-- value)	Return saved copy of Counter Register.
%lr	(-- value)	Return saved copy of Link Register.
%xer	(-- value)	Return saved copy of XER register.
msr@	(-- value)	Return current value of Machine State Register.
msr!	(value --)	Set new value of Machine State Register.
sprg3@	(-- value)	Get current interrupt vector pointer.
sprg3!	(value --)	Set our interrupt vector pointer.
.registers		Display the PowerPC CPU's saved program state.

NVRAMRC Editor Commands

nvalias <alias> <Device-pathname>
Store the command "devalias <alias> <Device-pathname>" in NVRAMRC. (The alias persists until the nvunalias or set-defaults commands are executed or NVRAM is reset.)

nvedit
Enter the NVRAMRC editor. If data remains in the temporary buffer from a previous nvedit session, resume editing the previous contents. If not, read the contents of NVRAMRC into the temporary buffer and begin editing it.

nvquit
Discard the contents of the temporary buffer without writing it to NVRAMRC.

nvrecover
Recover the contents of NVRAMRC if they have been lost

nvrun
Evaluate the temporary buffer.

nvstore
Copy the contents of the temporary buffer to NVRAMRC; discard the contents of the temporary buffer.

nvunalias <alias>
Delete the corresponding alias from NVRAMRC.

^c (Control-C) Quit nvedit and get back to the ok prompt.

Mac OS X Server: Workspace View Settings Not Remembered

Workspace windows always open in browser mode after setting them to either list or icon view.
This article has been archived and is no longer updated by Apple.
This is a known issue and is being investigated. Global settings in Workspaces preferences for views also do not work correctly

The only workaround is to set the view every time a window is opened.

AppleShare IP: International English Mac OS Included

I purchased the North American English version of AppleShare IP, but when I try to install the system software from the included disc, it asks me whether I want the British, Australian, or International English version installed.

This article has been archived and is no longer updated by Apple.

The International English version of the Mac OS ships with AppleShare IP. Simply install the International English (Z) version. Any of the three will work with AppleShare IP. If one of the other two versions is installed already, there is no functional need to go back and reinstall.

A/UX: TCP/IP Problem Configuration Solved

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

We have had a problem with A/UX and TCP/IP lines dropping. The problem configuration was:

IP: 192.31.38.69
Broadcast : 255.255.255.0
Netmask : 0

This article has been archived and is no longer updated by Apple.
The resolution to the problem is with the configuration of the /etc/NETADDRS file and the setting for the Broadcast address. The corrected configuration is:

IP: 192.31.38.69
Broadcast : 192.31.38.255
Netmask : 255.255.255.0

With this modification all line drops will be eliminated.

QuickTime 4: Description

This article describes the features of QuickTime 4.
This article has been archived and is no longer updated by Apple.
QuickTime 4: The easy way to play, create, and edit streaming movies, sound, pictures, and other media on Windows- and Mac OS-based computers.

Key Features

Versatile support for web-based media

- Access live and stored streaming media content with QuickTime Player
- View QuickTime movies more easily than ever with new enhanced controls
- View the most popular Internet media formats, including Macromedia's Flash format
- Save your favorite movies in the QuickTime Player for one-click access

Sophisticated playback capabilities

- Play back full-screen video
- Play slide shows and movies continuously
- Work with video, still-image, and sound files in all leading formats

Easy content authoring and editing

- Create new QuickTime streaming movies by copying and pasting content from any supported format
- Enhance movies and still pictures with filters for sharpening, color tinting, embossing, and more
- Save files in multiple formats, including the new DV format for high-quality video
- Create slide shows from pictures
- Add sound to a slide show

QuickTime is the most widely used cross-platform multimedia technology available today. QuickTime now has powerful streaming capabilities, so you can enjoy watching live events as they happen. The QuickTime 4 Pro version includes streaming capabilities as well as the tools you need to create, edit, and save QuickTime movies. These tools include QuickTime Player Pro, PictureViewer, and the QuickTime Plug-in.

QuickTime Player Pro has an exciting new look, easy-to-use controls, and the ability to save and bookmark your favorite movies, regardless of where they are stored. QuickTime Player Pro is ideal for viewing video and audio streams, animation, virtual reality scenes, and 3D models. It contains a convenient Favorites Drawer for one-click access to content, and it has sound-adjustment controls for balance, treble, and bass. You can also correct color, adjust contrast and brightness, and apply special effects such as film noise and lens flare to enhance your movies.

In addition to playing movies, QuickTime Player Pro can also open, edit, and save movies in dozens of different formats, including Macromedia Flash files. Flash is the Internet standard for interactive vector graphics and animation. With QuickTime 4 Pro, you can copy and paste Flash tracks from one movie to another; combine Flash tracks with video to create an interactive, user-controllable interface; and combine Flash tracks with other types of media. QuickTime Player Pro also has a new "LCD" panel that provides an easily accessible Timecode mode selector and a time slider for quick editing and saving.

Once you've finished editing, QuickTime Player Pro compresses your files using Sorenson Video 2, QDesign Audio 2, or Qualcomm PureVoice compressors for streaming from any Internet-ready web server. You can also choose one of the many standards-based compressors, such as H.263, to provide the ultimate in streaming media interoperability.

PictureViewer is an essential tool for viewing and converting images between standard publish-ing formats. It has enhanced support for still images, allowing you to rotate and resize more than a dozen of the most popular image file formats. Images can be saved in Photoshop or TIFF format for use by graphic artists, BMP or PICT format for use on Windows- or Mac OS-based computers, and PNG or JPEG for posting to your web site.

PictureViewer now supports the FlashPix multi-resolution standard created by Kodak, Hewlett-Packard, and Live Picture. With PictureViewer, you can open FlashPix files easily from a digital camera. You can also export to an image sequence to create your very own slide shows, or use PictureViewer to view 16-bit-channel images.

QuickTime 4 Pro includes the QuickTime Plug-in, which works with the leading web browsers to open any media type supported by QuickTime. The QuickTime Plug-in replaces numerous applications and plug-ins, allowing you to save movies and QuickTime movie favorites to media servers around the world by simply using the convenient plug-in "Save" control.

The QuickTime files you create can be viewed by anyone using a Windows- or Mac OS-based computer with QuickTime 4 installed. The files

will be displayed in exactly the same for mat as they were created. The QuickTime Player is included in QuickTime 4, but is not required to view QuickTime movies--many applications, such as word processors, web browsers, and presentation programs, can display QuickTime movies.

QuickTime 4 Pro offers a low-cost, simple, and powerful way to create, edit, and play media files on a computer. QuickTime 4 Pro applications work with all supported QuickTime media formats, making it easy to enjoy streaming media clips, movies, pictures, and sound files (including MP3 files) from the World Wide Web, DVD-ROM, CD-ROM, and other sources. No other product offers such a high degree of media integration.

Final Cut Pro 1.0: Specifications

This article outlines the specifications for Final Cut Pro 1.0.
This article has been archived and is no longer updated by Apple.
For system requirements, please see:

Article 60225 "**Final Cut Pro 1.0: System Requirements**."

Input and output formats

- DV video using FireWire
- Composite analog (NTSC) and component analog (NTSC) using Pinnacle Systems TARGA products or other certified QuickTime-compatible cards. (Final Cut Pro works with the Pinnacle Systems TARGA series of video capture cards. See www.apple.com/finalcutpro for information on other certified cards).
- All QuickTime video and file formats, including Motion and Photo JPEG, Sorenson, Cinepak, and more
- Standard image formats (BMP, JPEG, MacPaint, Photoshop, PICT, PNG, QuickTime Image, SGI, TARGA, TIFF) with alpha channels maintained (import only)
- Standard sound formats, including AIFF, WAV, and various compressions
- Export in QuickTime web-streaming format
- Import and export of common EDLs with preread options

Video capture

- Multiple resolutions and re-digitizing options
- Batch digitizing into bins
- Support for marking subclips during digitizing
- Ability to add scene, shot, take, and comment notations to footage as it is being digitized
- Waveform monitor

Printing to tape and exporting

- Instant playback of cuts
- Insert and assemble to tape using device control
- Up to 4,000x4,000-pixel resolution in any combination, including ITU-R 601 720x486-pixel and 720x576-nonsquare pixel options
- Compressed or uncompressed output
- 60-field processing
- Certified performance on Pinnacle Systems TARGA cards and other cards that have qualified QuickTime drivers. (Final Cut Pro works with the Pinnacle Systems TARGA series of video capture cards. See www.apple.com/finalcutpro for information on other certified cards).

Editing

- Three-point editing
- Match frame for replacing edits
- L cuts
- Multitrack trimming
- Multiple actions, including insert, overlay, and replace
- Ability to back-time edits in a single step
- Active track targeting
- Numerical trimming from timeline
- Slip trimming and slide trimming
- Support for editing and trimming using black (null) space, and for replacing black
- Sync multiple video edits to a single audio track
- Sync detection and automatic correction
- Markers with or without comments and durations
- Choice of editing with offline or online files
- One-step transition and superimpose edit mode
- Inline transitions instead of A/B model

Compositing and effects

- Direct manipulation of video and images
- Graphical and numeric control of acceleration and velocity

- Unlimited compositing layers
- Import of Adobe Photoshop files with layers maintained
- Subpixel motion accuracy
- Insertion of fully editable submasters
- Text generator
- Keyframe-based filters
- Real-time wire frame views
- Bezier motion path controls with acceleration control
- More than 75 built-in filters and keying effects
- Support for third-party Adobe After Effects plug-ins, including Ultimatte
- FXBuilder scripting language for creating custom filters and compositing effects
- Ability to apply effects to time ranges, not just clips
- Photoshop-like transfer modes, such as multiply and lighten
- Multiple compositing methods, including alpha, blue and green screen, luminance, and more
- Automatic alpha compositing
- Time effects such as slow motion with frame blending
- Motion blur and sophisticated image deinterlacing
- Multiprocessor rendering
- Four user-defined rendering qualities for fast previews
- Separate render cache for each quality setting
- More than 60 predefined transitions

Audio capabilities

- Sampling at 8 to 48 kHz and 8 to 16 bits
- Mixing of audio during video playback
- Audio pan controls
- Logarithmic audio fades
- Scrubbing with or without pitch shifting
- Automatic, single-step audio transitions
- More than 12 audio filters, including three-band and parametric equalizer, compressor/limiter, 60/120-Hz hum remover, and noise gate

Media management

- Multiple bins and folders for clip and effects storage
- Icon and detail list views by name and other parameters
- Ability to open multiple projects and programs
- Support for multi-item sorts, sifts, and searches
- Storage of clip information in 34 bin categories such as file size, frame rate, and comments
- Optional subclips

QuickTime 4: Where Do I Find Open Transport 1.2

The System Requirements section of the QuickTime 4 Read Me file, that I need "Mac OS version 7.1.1 or higher, with Open Transport 1.2 or higher." I have looked all around for Open Transport 1.2 and can't find it. Where can I get Open Transport 1.2?
This article has been archived and is no longer updated by Apple.
This section of the System Requirements needs a little clarification. Open Transport 1.2 is only required for QuickTime Streaming and is not required for normal playback of local movie files. However, the only way to install Open Transport 1.2 (or higher) is to install Mac OS 8 (or higher). Open Transport 1.2 is not supported on any version of the Mac OS prior to Mac OS 8 (the latest version of Open Transport that you can download for systems prior to Mac OS 8 is version 1.1.2).

So, just to clarify, here are the system requirements for QuickTime 4 slightly restated:

- Any Macintosh based on the 68020 processor (or higher)
- System 7.1.1 or higher
- 8MB RAM for 680x0 computer or 16MB RAM for PowerPC-based computers
- Streaming requires a PowerPC running Mac OS 8 (or higher) and a static IP address or a DHCP server

Published Date: Feb 18, 2012

QuickTime 4: FAQ

This article contains the following frequently asked questions (FAQ) regarding QuickTime 4, with answers to those questions.
This article has been archived and is no longer updated by Apple.
Questions answered in this article:

1. What's new in QuickTime 4?
2. How do I view streaming content?
3. How can I check if streaming is working?
4. What are the advantages of using QuickTime Streaming?
5. What is the difference between live and stored streaming?
6. What is the difference between QuickTime HTTP streaming and live streaming?
7. What is the difference between Apple's QuickTime streaming and existing streaming products such as RealPlayer from RealNetworks?
8. How can I create my own streaming multimedia?

Question 1: What's new in QuickTime 4?

Answer:

- New Enhanced Interface - View QuickTime movies more easily than ever with new enhanced controls. Save your favorite movies in the QuickTime Player for one-click access.
- QuickTime Streaming - QuickTime 4 supports live and stored video and audio streaming.
- QuickTime Web Installer - This release of QuickTime includes a totally new installer that improves the speed and flexibility of your installation process.

Question 2: How do I view streaming content?

Answer: Viewing QuickTime Streaming is as easy to view as QuickTime has always been. You have the ability of viewing a streaming movie in a web browser or QuickTime Player. In fact, any application that currently supports QuickTime 4 is capable of viewing QuickTime Streaming content.

Question 3: How can I check if streaming is working?

Answer: See the QuickTime Troubleshooting page: **http://www.apple.com/quicktime/troubleshooting/**

Question 4: What are the advantages of using QuickTime Streaming?

Answer: Using QuickTime Streaming as a solution allows you to utilize the QuickTime 4 features such as effects, chapter tracks, MIDI, alternate language tracks, poster effects, overlays, client-side transforms, and alternate data rate selections.

Question 5: What is the difference between live and stored streaming?

Answer: Live Streaming allows users to join a session in which real time media is being sent over a network. Because these streams are live, users are not allowed to jump around to any point in time. Unlike live streaming, video-on-demand, or stored streaming, allows users to jump to any point in time in the media.

Question 6: What is the difference between QuickTime HTTP streaming and live streaming?

Answer: The new live streaming capabilities of QuickTime 4 are complimentary to the QuickTime HTTP streaming that is currently built into QuickTime. QuickTime HTTP, otherwise known as Fast Start, downloads the entire QuickTime file to your computer. As soon as enough of the content has been downloaded, it will begin to playback the movie while downloading the rest of the file. QuickTime Streaming does not download the movie to the computer, but loads and plays the movie in real time as the data is received.

Question 7: What is the difference between Apple's QuickTime streaming and existing streaming products such as RealPlayer from RealNetworks?

Answer: Whereas RealNetworks uses proprietary streaming protocols, Apple has opted to use industry-standard streaming protocols such as RTP and RTSP. The use of industry standards encourages competition and advancement of the technology by multiple parties. QuickTime streaming also allows for effects, chapter tracks, MIDI, alternate language tracks, poster effects, overlays, client-side transforms, and alternate data rate selections.

Question 8: How can I create my own streaming multimedia?

Answer: If you have a Power Macintosh G3 or later, you can use Apple's QuickTime Streaming Server with Mac OS X. For more information, visit **http://www.apple.com/quicktime/streamingserver/**

QuickTime 4: Read Me

This is the Read Me included with QuickTime 4.

For clarification on system requirements, please see Knowledge Base article:

Article 60308: "**QuickTime 4: Where Do I Find Open Transport 1.2?**"

This article has been archived and is no longer updated by Apple.

QuickTime 4: The Standard in Streaming Digital Video

QuickTime is Apple's award-winning, industry-standard, software architecture for creating and playing digital media for Mac OS and Windows. With QuickTime 4, it is easier than ever to work with video, animation, sound, music, text, pictures, interactive images, and 3D graphics.

Macintosh System Requirements

QuickTime 4 requires a 68020 CPU or later running Mac OS version 7.1.1 or higher, with Open Transport version 1.2 or higher. Streaming functionality requires a PowerPC-based Macintosh. In addition, the computer must have at least 8 MB of RAM for 68K machines, and 16 MB of RAM for PowerPC systems, and either a static IP address or a DHCP server.

Windows System Requirements

QuickTime 4 runs on Windows 95, Windows 98 & Windows NT. Requires an Intel or compatible processor or any MPC2-compliant PC (minimum 66-MHz 486 or later processor). A Pentium processor is recommended when using effects, 3D, Sorenson Video, DV, Streaming, or Music. Requirements also include 16 MB of RAM, a Sound Blaster or compatible sound card, and speakers. DirectX version 3.0 or later is recommended.

What's New in QuickTime 4

QuickTime 4 provides dozens of new features and enhancements to existing features. For complete information about these new capabilities, including live video and audio streaming, support for Macromedia's Flash file format, and support for MP3 audio files, visit the QuickTime 4 web site at <**www.apple.com/quicktime**>. The QuickTime web site also provides many links to demonstration content and to other Internet sites that are using QuickTime.

One of the most innovative features of QuickTime 4 is its smart installation technology. With QuickTime 4, you will automatically be notified whenever updates to your QuickTime software are available. With a few simple clicks, you can quickly update your QuickTime software to the latest available version. You can also check for the availability of updated software manually. To perform this simple check, open the QuickTime Player application and select the menu item "Check for QuickTime Updates" found in the Help menu. Alternatively, you can open the QuickTime Updater application found in the QuickTime Folder and follow the instructions to install additional QuickTime pieces or to manually check for updates to your currently installed software.

About Roland's Sound Set for General MIDI and GS Format

This release of QuickTime includes an instrument sound set licensed from Roland Corporation that makes a complete General MIDI compatible sound set. It also includes additional sounds necessary to make a complete GS Format compatible sound set.

What is the GS Format?

The GS Format is a standardized set of specifications for sound sources that defines the manner in which multitimbral sound generating devices will respond to the MIDI messages. The GS Format complies with the General MIDI System Level - 1. The GS Format also defines a number of other details over and above the features of General MIDI. These include unique specifications for sound and functions available for tone editing, effects, and other specifications concerning the manner in which sound sources will respond to MIDI messages. Any device that is equipped with GS Format sound sources can faithfully reproduce both General MIDI sound recordings and GS Format MIDI sound recordings.

How to contact Roland:

Roland Corporation U.S.
5100 S. Eastern Ave.,
Los Angeles, CA 90040-2938

For more information about Roland and its line of products, visit the website at http://www.rolandus.com/.

Limitations

TA44327_QuickTime_Read_Me.pdf

Roland reserves all rights to the Sound Set not expressly granted by Roland Corporation U.S. or by Apple under the terms of Apple's Software Distribution Agreement.

Copyright Notices

Roland Corporation U.S. owns the Sound Set and all copyrights pertaining thereto and has licensed Apple to use the Sound Set solely in connection with Apple Products. Whenever this Sound Set, in whole or in part, is redistributed with an Apple Product, you must acknowledge Roland as the source in a user's standard point of entry to learn more about the product in use, such as in the "about" or "get info" dialog boxes. The minimum notice shall be "GM/GS(R) Sound Set (c) Copyright 1997 Roland Corporation U.S."

Mac OS X Server 1.x: G3 Firmware Update Installation

This article describes the G3 Firmware Update and the impact on Mac OS X Server users.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

There are minimal minimal performance enhancements, so it is not necessary to install this update when running Mac OS X Server.

The G3 Firmware Updater requires Mac OS 8.5.x or later installed on a read/write Mac OS Extended format volume. If Mac OS 8.5.x or later is installed on a Mac OS Extended format (HFS Plus) partition of your Power Macintosh G3 or Macintosh Server G3, it will be necessary to start up into it to install the firmware update.

Note: Macintosh Server G3 computers shipping from the factory with Mac OS X Server, do not include a Mac OS 8.5.x or Mac OS 8.6 System Sofware installer. A System Folder capable of starting up your computer may be found on your Mac OS format volume after installing Mac OS X Server.

Starting up into Mac OS 8.5.x can be performed by holding down the Option key at startup. Having started up into the Mac OS it will be necessary to decompress the downloaded updater file with Stuffit Expander or a similar MacBinary decompression tool. Once the file has been decompressed, proceed through the following instructions:

1. Double-click the Power Macintosh G3 Firmware Updater icon and follow the on-screen instructions.

2. Click the Shut Down button when a message appears telling you to shut down your computer.

Perform these steps after the computer has been shut down.

3. Hold down the Programmer's button on the front of the computer. (For more information, see the manual "Setting Up Your Power Macintosh G3" that came with your computer.)

Figure 1 Location of Programmer's button

4. Press the Power button on your computer or on the Apple USB keyboard while continuing to hold down the Programmer's button.

The computer starts up.

5. Release the Programmer's button when you no longer hear the tone.

A progress bar appears at the bottom of the screen.

6. After your computer starts up, if the update process was successful, a message appears saying the firmware is up-to-date. Click OK.

If a message appears saying the update was not completed successfully, go back to step 1 and begin the update process again.

If the Macintosh Server G3 or Power Macintosh G3 does not have an existing Mac OS 8 installation on a Mac OS Extended format partition, download the firmware update to a Mac OS Extended format partition. The following steps may be used to start up into Mac OS 8.5.x or later to apply the Firmware Update:

1. Start up from either the System Restore or Mac OS X Server Install discs that came with your Power Macintosh G3 or Macintosh Server G3 (Blue and White) computer.

2. Open your Mac OS format volume and locate the directory named *_NBS, where * is your Mac OS volume name.

3. Open the SharedImages folder and double-click on NetBoot HD.img.

4. After the NetBoot HD.img has appered on the desktop, copy the System Folder to the root level of your Mac OS Extended partition.

5. Remove the MM Client Startup Extension from the newly copied System Folder and set the volume as the startup disk in the Startup Disk control panel.

6. Decompress the downloaded updater file with Stuffit Expander or another suitable decompression utility, and proceed through the process described above for running the G3 Firmware Updater.

TA44329_Mac_OS_X_Server_x_G_Firmware_Update_Installation.pdf

Notes:

Because the firmware update requires booting into the Mac OS, refer to article 60217: "**Mac OS X Server: Choosing the Startup OS**"

If you are having difficulty starting up into Mac OS 8.5.x refer to article 60153: "**Mac OS X Server: Power Macintosh G3 (Blue and White) Won't Start Up With Mac OS 8.x**"

You should move the Mac OS System Folder on the Mac OS Extended format partition after completing the firmware update process.

G3 Firmware Updater 1.0.1: Crash After Installing Unformatted ATA Hard Drive

This article describes an issue with the G3 Firmware Updater that is included with Final Cut Pro 1.0.
This article has been archived and is no longer updated by Apple.
Final Cut Pro 1.0 includes G3 Firmware Updater 1.0.1 for the Power Macintosh G3 (Blue and White). It installs version 1.1f1 of Open Firmware. Apple has identified an issue with this version of Open Firmware that can cause the computer to crash at system startup time after an unformatted UltraDMA (ATA) hard drive is installed in the computer. (Crash does not imply that the hardware was harmed.)

This issue does not occur with the original version of Open Firmware that shipped with the Power Macintosh G3 (Blue and White). G3 Firmware Updater 1.0.1 is only available to users who purchase Final Cut Pro 1.0. The issue is resolved in G3 Firmware Updater1.0.2 or later, available from Apple Software Updates.

All Power Macintosh G3 (Blue and White) customers should download and install the latest firmware updater for their computer from the Apple Software Updates Web site at http://www.apple.com/swupdates/ even if they do not use Final Cut Pro.

For more information, see article 60314: "**Final Cut Pro 1.0: Download Newer G3 Firmware Updater**."
Published Date: Feb 18, 2012

Final Cut Pro: EDL Access For RT-11 Formatted Disks

Does Final Cut Pro support copying of Edit Decision List (EDL) files between the Macintosh file system and disks formatted with the RT-11 file system?

This article has been archived and is no longer updated by Apple.

Editing Systems manufactured by CMX and GVG (Grass Valley Group) use 90mm floppy disks that are formatted with a file system from Digital Equipment Corporation known as RT-11. These are 720K double-density disks.

Editing Systems manufactured by Sony Corporation use the DOS file format for their disks.

EDL Access(TM) from FocalPoint Systems, Inc. is a Macintosh application that can be used to format, read, and write to RT-11 formatted disks. EDL Access(TM) is included on the Final Cut Pro CD-ROM disc. Use EDL Access to copy an EDL file to or from a RT-11 formatted disk using a third party USB floppy disk drive. For Sony editing systems, you may copy the EDL file directly to a DOS formatted disk.

Definition: Beta Software, Beta Test

What is "beta" software, or a "beta test?"
This article has been archived and is no longer updated by Apple.
Beta is a term used to describe software that is in the last stage of testing. Software publishers frequently make beta software availabile to a limited audience so that it can be tested in real-world environments. This is called a beta test.

Because beta software may be incomplete, it may not function correctly all of the time. You should only install beta software if you know how to remove it, or how to troubleshoot errors it may cause. Before installing any beta software, be sure you have a backup of important files you want to keep.

iMac: Update Firmware Before Installing Mac OS 8.6

When I try to install Mac OS, the Installer gives me the following error:

"Your Mac's firmware is out of date, please update it before continuing."

What is firmware and how do I update mine?
This article has been archived and is no longer updated by Apple.
Firmware is the software that controls the basic functions of the iMac's hardware. Firmware is typically stored on a ROM chip or other controller chip on the logic board or other device within the computer.

Make certain that you have properly installed the iMac Firmware update prior to installing Mac OS 8.6 update. You will receive an alert message and the installation will be halted if you try to install on an iMac that has not been updated.

You can find the update in the CD Extras folder of the Mac OS 8.6 disc or you can download it from the Apple Software Updates Web site at http://www.apple.com/swupdates.

A list of all updates for each model of the iMac is available in document 58174 titled "**iMac: When to Install Available Updaters**"

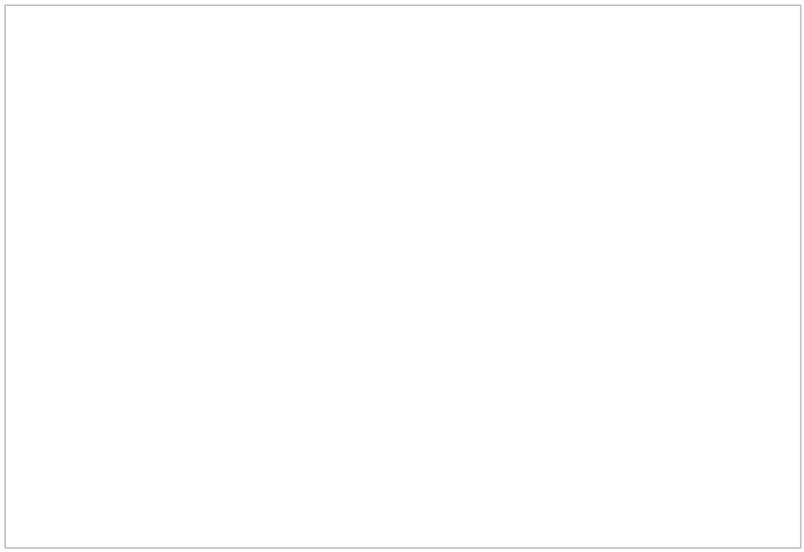
Mac OS 8.6: What‘s New - Sherlock 2.1

This article outlines the new features of Sherlock 2.1.
This article has been archived and is no longer updated by Apple.
Sherlock in Mac OS 8.6 has a number of enhancements:

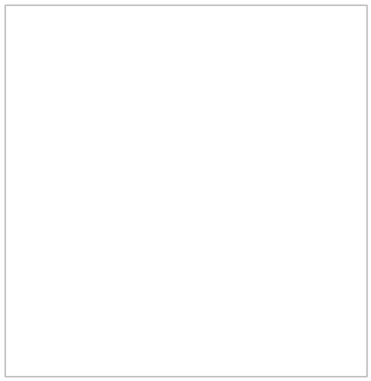
Search Internet

- Panel is now resizeable so you can easily see all available search sites
- The new Uncheck All button allows you to quickly deselect search sites.
- Improved ability to search behind firewalls, including SOCKS and authenticated proxy servers.



Find by Content

- Allows indexing and searching of PDF and HTML files.
- Can index or search items with a specific label
- Can index the contents of a specific folder (instead of the whole disk) using the contextual menu:



Preferences

- Preferences allow setting the number of Internet connections that you can make simultaneously:

Mac OS 8.6: What‘s New - LaserWriter 8.6.5

This article outlines the features of LaserWriter 8.6.5.
This article has been archived and is no longer updated by Apple.
LaserWriter 8.6.5 provides support for secure printing using AppleShare IP 6.1 and works with USB-connected PostScript printers. The LaserWriter 8.6.5 print dialog box allows you to create a Job/Font log to view a history of your printing jobs and fonts used. You can also choose TrueType over Type 1 fonts and force all fonts to be downloaded to the printer.

When you select Print from the File menu of any application, you get the print dialog box shown here. The different menu options appear in the Print Options pop-up menu. The Print Options pop-up menu is under the word "Printer." Selecting Font Settings from the print options menu provides the window shown here:

Font Settings options

- Select the Annotate Font Keys checkbox to annotate font keys in the PostScript output. This will include information regarding the QuickDraw font (which the driver has translated into a font for the printer, either a PostScript Type 1 or TrueType font). The information may be used by a very sophisticated user (such as a prepress user) to debug a troublesome print job.
- Select either Type 1 or TrueType radio buttons in order to select which font type is preferred.
- Select the Always download needed fonts option to ignore fonts in the printer's ROM or memory.
- Select Never generate Type 42 format to prevent Type 42 fonts. A type 42 font is a TrueType font. Some high end printers do not work with TrueType fonts. This option provides a way to force the driver not to generate TrueType fonts at all. If one is needed, the TrueType font is converted into an unhinted Type 1 font. (This is not the best font, but it will print.)

Note: The vast majority of users and print jobs do not need to change (or benefit from changing) the Font Downloading options. If you have changed these options from their defaults and you are experiencing printing difficulties, try restoring the options to their defaults by clicking the Use Defaults button (see above).

Selecting Job Logging from the print options menu provides the window shown in here:

Job Logging options

PostScript error reporting is sometimes useful in determining why a print job has failed when the printer fails to print.

- Select No special reporting to prevent reporting of any PostScript errors during printing.
- Select Summarize on screen to receive a summary of any PostScript errors encountered during printing.
- Select Print detailed report to print a detailed description of any PostScript errors encountered during printing.
- Select the Generate Job Copy and/or Generate Job Log options to see PostScript error reporting information in the job log.
- Click the Change button to select a destination folder for font logs and job copies.

To receive explanations of each of the settings in the LaserWriter 8.6.5 print dialog, select "Show Balloons" from the Help menu before selecting the Print command. Help balloons appear as you move the pointer over each setting.

Published Date: Feb 18, 2012

Mac OS 8.6: What's New - Dvorak Keyboard Layout

This article describes the new features of the Keyboard control panel 8.2, including the Dvorak keyboard layout.
This article has been archived and is no longer updated by Apple.
Additional keyboard layouts have been added to Mac OS 8.6 to support Dvorak keyboards. A Dvorak keyboard is a keyboard whose keys are in different order than standard keyboards. For example, standard American keyboards start with the letters QWERTY. A Dvorak keyboard starts with the characters ',.pyf.

Dvorak keyboards are designed to be easier and quicker to use and with fewer mistakes. Using a Dvorak keyboard involves having to relearn how to type. The keyboard layout is a way that to get the functionality of a Dvorak keyboard without having to buy a Dvorak keyboard.

To select the Dvorak keyboard layout:

1. Open the Keyboard control panel.
2. Click the checkbox for Dvorak or Dvorak - Qwerty to select the keyboard layout.
3. Clicking the Options... button will allow you to specify Keyboard Menu Shortcuts used to toggle between selected keyboard layouts.

Published Date: Feb 18, 2012

Mac OS 8.6: What‘s New - English Speech Recognition 1.5.4

This article outlines the new features of English Speech Recongnition 1.5.4.
This article has been archived and is no longer updated by Apple.
English Speech Recognition 1.5.4 is software that allows the computer to interpret your speech and run Speakable Items scripts. New features in version 1.5.4 include:

- Support for 44.1 kHz sound input used on iMac and G3 series computers has been added.
- The Speakable item script "Find by content" that references "Find" rather than "Sherlock" has been corrected to reference "Sherlock".
- The Speech Recognition extension now correctly restores the sound input source to it's original state when exiting. In previous versions of Speech Recognition, users may have noticed some feedback being generated during shutdown.

QuickTime 4: Rescanning MIME Types

This article describes how to rescan the MIME settings used by the QuickTime Plug-in.
This article has been archived and is no longer updated by Apple.
You can rescan QuickTime Plug-in MIME settings from within your browser by doing the following:

1. Drag and drop the file Sample.mov installed by the QuickTime installer into your browser window.
2. Click and hold down the mouse button on the movie. A pop-up menu appears.
3. Select Plug-In Settings. The following screen appears:

4. To reset the MIME types the plug-in uses click on MIME Settings... The following screen appears:

5. Click the checkbox for the MIME type you want the QuickTime Plug-in to handle, then click the OK button. The following message appears:

6. Click the OK button twice to reach the Plug-In settings window.
7. Click Save to keep the changes you have made.

Published Date: Feb 18, 2012

QuickTime 4: Using QuickTime Player

This article describes the QuickTime Player application program and how to use it.
This article has been archived and is no longer updated by Apple.
The MoviePlayer application previously included with earlier versions of QuickTime has been updated and renamed QuickTime Player. QuickTime Player provides a dramatically new user interface and features, as well as support for viewing QuickTime Streaming files.

To open QuickTime Player, double-click its icon in the QuickTime folder.

Player Window

When opening the QuickTime Player, a new Player Window appears:

The controls and features of the Player Window are:

A - Close box - closes the Player window
B - TimeCode Display - this shows the current time in hours, minutes, and seconds from the beginning of the movie
C - Volume control - can be rotated to control the volume level.
D - Volume level indicator - displays a graphical representation of the current volume level.
E - Name of the QuickTime file
F - Time bar - represents the duration of the movie, can be dragged to change the current time.
G - Information button - clicking this button displays the Info Panel. The Info Panel displays copyright and author information of the QuickTime file being viewed. **Note**: Not all QuickTime files will contain copyright or author information.
H - Controls button - clicking this button displays Playback Controls for adjusting the sound and navigating the movie.
I - Window size - Click and drag the corner of the Player Window to adjust the size of the window. **Note**: the window size is always a minimum of 320 x 240 pixels. If the movie size is smaller than this, it will be centered in the Player Window.
J - Play button - Click this button to begin playing a movie from its current time. Click again to stop playing.
K - Favorites Drawer - Click and drag this control to open the Favorites Drawer. Double-click the control to quickly open and close the drawer.
L - Pause button - Click once to pause the movie playback. Click the Play button (J) to resume playback.

Playing a QuickTime Streaming Movie

In addition to QuickTime files on your computer, QuickTime Player can also open and display QuickTime Streaming movies. These movies can be either fast-start (HTTP) or streaming (RTSP) movies.

Note: You must have an active connection to the Internet in order to view QuickTime Streaming files.

From the File menu, select Open URL... and type the full URL address of the QuickTime streaming file:

Click the Ok button. QuickTime Player makes a connection to the Internet server URL address you have typed and opens a new window.

Status messages are displayed in the window to the right of the timecode display. After successful connection to the server, the movie will begin playback.

You must type the full Internet service type designation of rtsp: in the URL address to access files on a QuickTime Streaming web server. Other service types supported are http: and ftp.

If you receive the message "Can't find movie on server," check that you have entered the full path to the movie including upper and lowercase characters.

Favorites Drawer

The Favorites Drawer allows you save bookmarks to QuickTime files on your local hard disk or on QuickTime Streaming Servers. The favorites bookmarks can be used to quickly open the QuickTime file. To access the Favorites Drawer, double-click its handle at the bottom of the Player window:

To create a bookmark of a movie that you have opened, select Add Favorite from the Favorites menu. An icon representing the QuickTime movie favorite appears in the Favorites drawer.

You can add bookmarks to the Favorites drawer by dragging the QuickTime file's icon from the Finder to the Favorites Drawer.

- To access a movie from the Favorites drawer, just click on its icon.
- To arrange bookmarks, click and drag its icon to a new location within the Favorites drawer.

To close the Favorites Drawer, double-click its handle at the bottom of the Player window.

Mac OS 8.6: Installing Mac OS 8.6

This document provides compatibility information and basic troubleshooting for installing Mac OS 8.6.
This article has been archived and is no longer updated by Apple.

Before you install

1. Make sure you have at least 24 megabytes (MB) of RAM installed in your computer.
2. Turn off any security software that you may have installed on your computer.
3. If you have a PowerBook, make sure that it is plugged into an AC power outlet and set not to go to sleep.
4. Start up your computer using the Mac OS CD. (Hold down the "C" key while you restart). If you're installing from a network or your computer does not have a CD-ROM drive, you should turn off any virus-protection software and non-Apple extensions and control panels that you may have installed, then restart your computer. See the installation manual for details.
5. It's recommended that you do an easy installation to update your system software. If you plan to do a clean installation instead, write down your current Internet settings, such as the IP address, subnet mask, name server, and so on from the TCP/IP, PPP or Remote Access, and Modem control panels. After installation, the Internet Setup Assistant will ask you to enter this information. (If you do an easy installation, you do not need to write down this information.)
6. If you are the administrator for a NetBoot-capable server, before you install Mac OS 8.6, please go to the Apple support Web site in the Mac OS X server section at: http://www.apple.com/support/ for the latest version of the NetBoot Desktop Admin and follow the instructions in the related Read Me.
7. Although compatibility issues are not expected, check with the manufacturers of any non-Apple software you use to make sure it is compatible with Mac OS 8.6. For information on isolating compatibility issues, see the troubleshooting section in this document or the troubleshooting chapter in your installation manual.
8. Review the compatibility information in this document.

Compatibility information

- Installing Mac OS 8.6 on computers with Ultra Wide SCSI cards
  Some older Ultra Wide SCSI cards require a firmware update before they will work with Mac OS 8.6. If the card's firmware is not compatible, your computer will crash during installation or when you start up from the CD. Before installing Mac OS 8.6, contact the manufacturer of your SCSI card to determine if a firmware update is necessary.

- Internet Setup Assistant and LAN connections
  If you connect to the Internet over a local area network, select the "add a new Internet configuration" option when you use the Internet Setup Assistant. (Selecting the option to modify the default configuration will not configure your TCP/IP settings correctly.)

- Third-party Finder and utility software
  Some third-party programs that extend or add features to the Mac OS may not be compatible with Mac OS 8.6. Examples include programs that change the way menus work, change how files are stored, or alter the way you work with files in the Finder. You may need to upgrade these applications before you can access the files they affect. For more information, contact the third-party software manufacturer.

- Computers with DOS compatibility cards
  Apple DOS Compatibility cards do not work with Mac OS 8.6.

- Computers with PowerPC processor upgrade cards
  Computers with 680x0 processors that have been upgraded with a PowerPC processor upgrade card do not work with Mac OS 8.6.

- 400K floppy disks and Mac OS 8.6
  The 400K MFS disk format is not supported by Mac OS 8.6. If you have information or programs on 400K disks that you want to access, copy the files to your hard disk or another storage device before installing Mac OS 8.6.

- QuickDraw GX and Mac OS 8.6
  After installing Mac OS 8.6, you may not be able to print from application programs that use QuickDraw GX. For more information, see About QuickDraw GX on the Mac OS 8.6 CD.

- MacODBC and Mac OS 8.6
  If you use MacODBC, you should either install it before installing Mac OS 8.6, or perform a custom install of MacODBC and make sure the ASLM extensions are not selected. The MacODBC installer installs older versions of ASLM extensions that are incompatible with Mac OS 8.6.

- Installing Mac OS 8.6 on accelerated NuBus PowerPC computers
  If you have a Power Macintosh 6100, 7100, 8100, or 9150 with a third-party accelerator card installed, the Installer might not install Mac OS 8.6. For more information, contact the accelerator card's manufacturer.

- Performa or Power Macintosh 5000 and 6000 series computers
  Some Performa or Power Macintosh 5200, 5300, 6200, and 6300 series models cannot use Mac OS 8.6 until a hardware issue is fixed. The repairs are covered under the Apple repair extension program. To see if your computer has this hardware issue, use the 5xxx/6xxx Tester utility in the Utilities folder on the CD before installing Mac OS 8.6.

  IMPORTANT The Power Macintosh or Performa 5260, 6320, and 6360 do not have this hardware issue. You do not need to use the tester program if you have one of these computers.

Troubleshooting suggestions

If you experience issues during installation, be sure you have started up with the Mac OS CD. See your installation manual for further instructions. You can also check the following:

Updating your disk drivers
Some Apple-brand disks manufactured by third parties, including the Apple 365 MB external hard disk, are not supported by the Apple disk utilities. If your disk cannot be updated with the Apple utilities, you will need to use a third-party disk utility to update the driver.

Repairing disks
If you see a message that your disk has issues and cannot be repaired, make sure file sharing is off, then try installing again. If that does not work, try using another disk-repair utility. If that utility also does not work, you may need to reinitialize the disk. Before doing so, copy all your files to another disk as reinitializing erases the disk. For more information, see Mac OS Help in the Finder's Help menu.

Updating your firmware
If you receive a message during installation that your firmware is out of date, follow the instructions for updating your firmware in the CD Extras folder on your Mac OS CD, or at the Apple support Web site: http://www.apple.com/support/imac/.

Installing over a network
If you are installing over a network, or if you have a non-Apple CD-ROM drive and cannot start up with the CD, turn off all extensions that were not provided with your system software. Then restart the computer. For instructions, see your installation manual.

Additional troubleshooting information is available in the Mac OS installation manual. For up-to-date news and compatibility information, go to the Mac OS Late-Breaking News Web site at http://www.info.apple.com/latebreakingtips/.

Apple IIGS System 5.0: Setting Up an AppleShare Network

I have been having problems adding Apple IIGS systems to an AppleShare network under Apple IIGS System Software Update Version 5.0. Can you give me some help?
This article has been archived and is no longer updated by Apple.
The following information applies to Apple IIGS System Software Version 5.0 and later.

Because of recent rapid development of the Apple IIGS operating system, setting up an AppleShare network with IIGS systems can be confusing. For example, the Apple II Setup disk included with AppleShare Version 2.0.1, a Macintosh disk designed to install Apple II features onto the Macintosh file server, is now obsolete. You should use the Apple II Setup disk that comes with the Apple IIGS System Software Update Version 5.0 and later. If you do the AppleShare installation with the obsolete Apple II Setup disk from AppleShare Version 2.0.1, you get the following error message when you try to start an Apple IIGS over the network:

Cannot load (servername) /SYSTEM/SYSTEM.SETUP/CDev.Init.

To add IIGS systems to an AppleShare network properly under Version 5.0, you must buy the Apple IIGS System Software Update Version 5.0 or later. The update package includes the Apple II Setup disk and the manual "AppleTalk Network User's Guide for the Apple IIGS."

Setting up AppleShare on the Macintosh Server

Follow the steps below to set up AppleShare, so that IIGS systems start over the network.

1) Start up with the System Tools disk and run Apple HD SC Setup.

2) Initialize the server hard disk.

3) Name the hard disk using an Apple II convention; for example, "A2." (The shorter the name, the better.)

4) Install the Macintosh System Software on the server, making sure to use the latest version possible for your Macintosh computer.

5) Restart with the AppleShare Version 2.0.1 Server Installer disk. Install "AppleShare 2.0.1 Server" onto the server volume. Be sure you don't click any of the Macintosh-family installation scripts, because they will install old system software, overwriting the system software you just installed.

6) Restart from the AppleShare Server Admin disk and launch the Server Admin application.

7) Enter the administrator's key and password, name your server, and create the users and groups you need.

8) Choose Volume List from the Volumes menu and double-click the server volume. A dialog box allows you to set access privileges. Click all boxes and save enclosed folders.

9) Quit the Server Admin application and restart the Macintosh server from the Apple II Admin disk that came with the Apple IIGS System Software Update Version 5.0.

10) Launch the Installer program on the Apple II Admin disk, and install "Apple II Info" on the server volume; then quit.

11) Restart from the Server Admin disk and launch the Server Admin application.

12) From the Server menu, choose Server Info and click the Apple II feature. Then, click Save.

13) Choose Volume List from the Volumes menu and double-click the server volume. A dialog box allows you to set access privileges. Click all boxes and save enclosed folders.

14) Quit the Server Admin application and restart the server. Keep the server on-line while you perform the steps for the Apple IIGS.

Setting up AppleShare on the Apple IIGS

Follow the steps below to set up AppleShare on the IIGS systems:

1) Start up with the System.Disk that came with the Apple IIGS System Software Update Version 5.0, and format a blank 3.5-inch disk.

2) Launch the System 5.0 Installer on the System.Tools disk.

3) In the Installer, select "AppleShare on 3.5 Disk" and install it on the formatted disk. (You'll have to do some disk swapping.)

4) Shut down the IIGS and restart from the AppleShare 3.5 disk you just created.

5) Enter the administrator's name (usually "Administrator") and password. On the Graphic Control Panel under the Apple menu, click the AppleShare icon and mount the server volume.

6) Launch the Installer program on the IIGS System.Tools disk.

7) Using the Command key (Open Apple), select the following scripts:

* Latest Sys. Files (No Finder)
* Server Network Startup
* Server Quick Logoff
* Optional scripts (Install the scripts that the IIGS systems starting up over the network will require; for example, the SCSI driver, 5.25 driver, LaserWriter printer, or AppleTalk printer.)

8) Install the selected scripts on the server volume. The system installs over the network, and the double-arrow icon at the top left of your screen flashes. You may have to do some disk swapping, and the installation may take a fair amount of time.

9) Once the installation is complete, quit and shut off the IIGS.

10) Shut down the file server and restart it from the Server Admin disk.

11) Launch the Server Admin application.

12) Select all users, or all Apple IIGS users who you want to be able to start up over the network.

13) Under the Apple II menu, choose Set Startup, and designate "Finder" as the startup application. (It will be located at /servername/System/Finder.)

14) When you're prompted for a response, allow the system to set the prefix automatically.

15) If the users you selected will be using a network printer, select Set Printer.

16) Choose Volume List from the Volumes menu and double-click the server volume. A dialog box allows you to set access privileges. Click all boxes and save enclosed folders.

17) Quit the Server Admin program and restart the file server.

18) On the IIGS units that you want to start up over the network, reset the startup slot from the Control Panel. Systems with ROM 01 should have the printer port set to "Your Card," Slot 7 set to "Built-in AppleTalk," and the startup slot set to "7." Systems with ROM 03 should have the printer port set to "Built-in AppleTalk," Slot 7 set to "Built-in AppleTalk," and the startup slot set to "AppleTalk."

Note: If you have the newer model Apple IIGS with 1MB of RAM on the logic board, set Slot 7 to AppleTalk and EITHER slot 1 or slot 2 to AppleTalk.

19) Restart the Apple IIGS. It now boots over the network and prompts you to enter a user name and password. Once you enter the name and password, the "progress thermometer" appears, and then you see the Apple IIGS System 5.0 desktop with the server volume icon at the top right.

Mac OS 8.6: What‘s New - AppleShare Server Messages

After upgraded to Mac OS 8.6, you may see files on the desktop named "AppleShare Server Messages."

This article has been archived and is no longer updated by Apple.
This is a new feature in Mac OS 8.6. AppleShare servers alert connected clients whenever there is a change in network status (if a server shuts down, for example). These alerts now time out. After a two-minute delay, the alert is dismissed and the message text from the alert is appended to the end of the "AppleShare Server Messages" file located on the desktop. If the AppleShare Server Messages file is not on the desktop, a new file is created.

Mac OS X Server: Updating the NetBoot Mac OS ROM File

When updating the NetBoot HD.img file with the NetBoot Desktop Admin for the purposes or installing a newer version of the Mac OS you do not have to separately update the Mac OS ROM file in the Shared Images folder.

This article has been archived and is no longer updated by Apple.

The NetBoot Desktop Admin application will check to see if the Mac OS ROM file was modified when changes to the NetBoot images are saved. If it was modified as is the case with the Mac OS 8.6 update, it copies the new Mac OS ROM file to the shared images directory automatically.

Open Transport 2.0 Technical Information - Part 2

This document contains technical information about Open Transport that may be useful to network managers and administrators. You do not need to read this document in order to use Open Transport.

Refer to article 58138: "**Open Transport 2.0 Technical Information - Part 1.**" for the first part of this article.
This article has been archived and is no longer updated by Apple.

Contents

- Dialup network connectivity - AppleTalk
- Dialup network connectivity - TCP/IP
- Native dialup network connectivity - AppleTalk
- Native dialup network connectivity - TCP/IP
- MDEVs
- Tips for SLIP and PPP configurations

Dialup network connectivity - AppleTalk

For dialup connectivity to AppleTalk networks, Open Transport supports Apple Remote Access version 2.0.1 or later.

Dialup network connectivity - TCP/IP

For dialup connectivity to TCP/IP networks (including the Internet) Open Transport supports third-party extensions known as "MDEVs." Serial Line Interface Protocol (SLIP) and Point to Point Protocol (PPP) connectivity are provided in this manner. Not all versions of all MDEVs are compatible with Open Transport 1.1 and later.

Native dialup network connectivity - AppleTalk

Apple Remote Access - version 3.0 or greater
ARA 3.0 supports AppleTalk and TCP/IP protocols concurrently over a PPP connection and is also compatible with ARA 2.x family clients and servers.

Native dialup network connectivity - TCP/IP

Apple Remote Access - version 3.1
ARA 3.1 offers the same features as OT/PPP for dialup access to a TCP/IP network.

OT/PPP - version 1.0 or later
OT/PPP is available on the Apple Software Update sites on the Internet and requires Open Transport 1.1.1 or later.

MDEVs

Open Transport 1.1 and later recognizes and is compatible with the following MDEVs. When properly installed they appear in the "Connect via" pop-up menu in the TCP/IP control panel.

FreePPP - version 1.0.5 or later
FreePPP is shareware and can be found on the Internet at the following sites: ftp://mirrors.aol.com/pub/info-mac/comm/tcp/conn/, and ftp://mirror.apple.com/mirrors/Info-Mac.Archive/comm/tcp/conn/.

FreePPP versions prior to 2.5 may experience problems when running with virtual memory turned on (including RAM Doubler). If you have problems using FreePPP with VM, either update to FreePPP 2.5, or temporarily turn VM off. The current version of FreePPP is 2.6. The FreePPP home page provides the latest information about FreePPP at http://www.rockstar.com/ppp.shtml.

MacPPP - version 2.1.4 or later (MacPPP 2.5 or later is recommended)
MacPPP versions prior to 2.5 may experience difficulties when running with virtual memory turned on (including RAM Doubler). If you have problems using MacPPP with VM, either update to MacPPP 2.5, or temporarily turn VM off. An Open Transport-compatible version of MacPPP (MacPPP 2.5) is included in the Open Transport Extras folder. For more information, please refer to the MacPPP Read Me document.

InterPPP II - version 1.1 or later
InterPPP II is a commercial software product. It has been replaced by CONNECT4ppp which is part of tcpCONNECT4. tcpCONNECT4 can be purchased from VisionSource at 800.326.7427. Additional information is posted on the InterCon web page at http://www.intercon.com.

MacSLIP - version 3.0.4 or later
MacSLIP is commercial software developed by Hyde Park Software. For availability and ordering information in the U.S., contact TriSoft at 800-531-5170 or 512-472-0744. For more details see the MacSLIP Web page at http//www.zilker.net/~hydepark/.

Sonic PPP - version 1.0.2 or later
SonicPPP is commercial software developed by Sonic Systems, Inc. For availability and ordering information in the U.S., contact Sonic Systems at 408-736-1900 (voice) 408-736-7228 (fax). For more details see the Sonic Systems Web page at http//www.sonicsys.com/.

NTS PPP - 2.0 or later
NTS PPP is commercial software developed by Network Telesystems, Inc. For availability and ordering information in the U.S., contact Network Telesystems at 408-523-8100 (voice) 408-523-8818 (fax). For more details see the Network Telesystems Web page at http//www.nts.com/.

LAN TunnelBuilder is a Virtual Private Network technology from NetworkTelesystems, Inc. For more details see the Network Telesystems web page at http://www.nts.com/.

SAT/SAGEM PPP - 1.02b1 or later
SAT/SAGEM PPP is commercial software developed by SAT/SAGEM. For availability and ordering information in the US, contact SAT/SAGEM at 408-446-8690 (voice) 408-446-9766 (fax). For more details see the SAGEM Web page at http//www.satusa.com/.

LeoTCP - 2.0.1 or later
LeoTCP is commercial software developed by Hermstedt GmbH. For availability and ordering information in the U.S., contact Hermstedt USA at 1-800-828-5522 (voice). In Europe contact Hermstedt GmbH at +49 621-76500 (voice) +49 621-7650100 (fax).

T-Online CSLIP - version 1.0.3 or later
T-Online CSLIP is commercial software developed by Computer Consulting GbR. For availability and ordering information in Europe, contact format network & communication at 49 2206 95840. For more details, contact format network & communication at info@format.de.

University of Michigan ISDN - 2.0.6 or later
In addition to these, there are a number of other MDEVs (examples include those from Pacer, FCR, and Tribe) which are indistinguishable from one another to Open Transport. When installed, these appear in the "Connect via" pop-up menu as "TCP/IP PPP."

AOL Link
AOL Link is commercial software developed by America OnLine. It is part of the America OnLine client software that is available from AOL's ftp site and allows use of MacTCP or Open Transport compatible TCP/IP applications while connected to AOL. The latest version of the AOL client is on the AOL ftp site at ftp://ftp.aol.com/.

CompuServe PPP is a commercial PPP implementation specifically designed for connecting to CompuServe. You can obtain it from the CompuServe web site at http://www.compuserve.com/.

Tips for SLIP and PPP configurations

Some MDEVs are known to be incompatible with other MDEVs. If you experience problems, remove unused MDEVs so that only the MDEVs you need are installed on your computer at a given time. If you still encounter problems, you may have to reduce the number of MDEVs installed to one to prevent conflicts.

Users who dial into a TCP/IP network or Internet Service Provider (ISP) may have been assigned a router (gateway) address that is not a part of their local subnet. This was an accepted but technically invalid configuration for MacTCP. Open Transport users should not enter a value for the router address or subnet mask; Open Transport/TCP generates correct values for these fields automatically. In unusual circumstances, these supplied values can be overridden using the Administration mode of the TCP/IP control panel.

If BootP is used over SLIP or PPP for interface configuration, and if BootP returns additional default router addresses, Open Transport will automatically add those addresses to the list of default routers.

When Open Transport is installed on a computer that previously had MacTCP configured for a server configuration, the initial configuration method--the selection in the "Configure" pop-up menu in the TCP/IP control panel--is set for the use of a BootP server. This default may not be the appropriate choice for you; please verify.

If your computer was previously configured for MacTCP "server" addressing and you experience connection difficulties using PPP or SLIP after installing Open Transport, follow these steps:

1. Open the TCP/IP control panel.
2. Choose Using PPP Server or Using SLIP from the Configure pop-up menu.
3. Close the TCP/IP control panel, and save changes when prompted.
4. Try connecting again.

If your computer was previously configured for MacTCP "manual" addressing and you experience connection difficulties using PPP or SLIP after installing Open Transport, follow these steps:

1. Open the TCP/IP control panel.
2. Choose Manual from the Configure pop-up menu.
3. Verify that the correct IP address is entered in the Address field.
4. Close the TCP/IP control panel, and save changes when prompted.
5. Open the configuration utility supplied with your SLIP or PPP software, and verify that it also reflects the correct IP address in the appropriate location. Refer to the documentation supplied with your SLIP or PPP software for further information on how to enter an IP address, and how to save an updated configuration.
6. Try connecting again.

Note: In MacPPP's ConfigPPP control panel, this setting is entered in the IPCP dialog box. Refer to the documentation that came with MacPPP or FreePPP for additional information.

A/UX: The Event Manager and Mouse Events

Article Change History

08/31/92 - REVIEWED
*For technical accuracy

I'd like to share a general observation, concerning A/UX and multitasking support while running the Finder.

While it is true that A/UX provides true pre-emptive multi-tasking for processes on the machine, it is also true that when the mouse button is held down, all activity appears to cease. The customer observation here is that the computer halts everything to deal with the mouse being down, and nothing seems to happen during this time.

What little I know about Macintosh development and priority queues tells me that StillDown events are taking precedence over screen update events. Therefore, the machine seems to stop. Although, in reality, it continues to process other tasks. Typical workstations have different priorities for user events, and, therefore, tasks continue to run and change their displays despite the actions of the user. Potentially, this could affect the responsiveness of the machine to the user, because user actions are not assigned any special priorities.

Is this is correct?

This article has been archived and is no longer updated by Apple.
Your observations are correct. The Event Manager always returns the highest priority event waiting in the queue. When using A/UX, even though it looks like processing has stopped when you hold down the mouse button, it still is continuing to give processor time to other processes. This is handled by the A/UX scheduler process and falls outside the realm of the Finder shell.

The Event Manager priorities are defined as follows:

1) Activate (window becoming inactive is higher than window becoming active).

2) Mouse down, mouse up, key down, key up, disk inserted, network, device driver, application defined (in that order).

3) Auto key.

4) Update (in front-to-back order of the windows).

5) Null.

To demonstrate this, you could use the small shell script that follows:

1) Start up this process.

2) Let it count up to 10.

3) Press and hold the mouse button. The screen stops updating. The log file will continue to be updated (you will continue to hear the drive).

4) While still holding the mouse button down, press Control-C. Screen output from the program should be halted from the time you first pressed the mouse button down, somewhere around 10.

5) Open the log file (/tmp/junk.log). It shows that the file was being updated even though the screen was not.

C Shell Script

```
#! /bin/csh

set counter = 1

while (1)

echo "The counter value is " $counter | tee -a /tmp/junk.log

@ counter++

end

exit 0
```

QuickTime 4: Does Not Work With Avid Cinema 1.2.2b

Avid Cinema version 1.2.2b does not work with QuickTime 4.
This article has been archived and is no longer updated by Apple.
Included with Apple's Teacher's Workstation bundle is Avid Cinema 1.2.2b which can be used to record video in conjunction with the ATI Xclaim VR video card. This configuration comes with QuickTime 3 installed. Until a newer version of Avid Cinema is released to work in this configuration, do not install QuickTime 4. Avid Cinema 1.2.2b will not record video if QuickTime 4 is installed and may cause the computer to stop responding.

Other versions of Avid Cinema (including 1.2.2 and 1.3)continue to work with QuickTime 4.

Mac OS X Server 1.x: Wrappers

When using the Terminal application MacOS.app is actually a directory with a MacOS executable inside it. This article explains the difference between the MacOS.app directory and the MacOS executable.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

In this case, MacOS.app is a wrapper. A wrapper is a directory that contains an executable and any resources the executable may need to operate. Wrappers contain the kind information that would be stored in the resource fork of a Mac OS 8 application, such as icons. Resource forks can not be used with Mac OS X Server because the UFS directory structure does not support forked files.

The Workspace Manager makes directories ending in .app, .pkg, or .mpkg wrappers and thus double clickable. The command line does not have this functionality which is why this difference is noticeable.

Wrappers can be opened by holding down the Command+Shift+O keys, or by holding down Command+2 and pressing the Open Application Wrapper button.

Older command line utilities like the ones in /bin and /sbin do not have a wrapper because they do not have a graphical interface, and therefore must be executed at the command line.

AppleShare IP 6.x: MacDNS Tutorial on Disc Has Broken Images

The MacDNS tutorials on the AppleShare IP 6.0, 6.1, and 6.2 discs have two pages that contain HTML errors.

This article has been archived and is no longer updated by Apple.
The following pages are affected:

- index.html - this page is missing the background image.
- overview.html - this page is missing the background image and all other images.

Although these pages have HTML code errors, their content intact and they contain correct information. This cosmetic issue should not limit the effectivness of the tutorials.

AppleShare IP 6.2 Help Files On Disc Don‘t List Table of Contents

The left half of the page of the AppleShare IP Help file from the 6.2 disc is blank.
This article has been archived and is no longer updated by Apple.
The AppleShare IP Help Files are designed to be run from the System Folder of your AppleShare server. They are installed there when you install AppleShare IP, and they are also present on the disc in the form of a disk image. If you attempt to access the files on this image, the Table of Contents frame is missing.

To see the full content of the files, access the copies that are installed in the Help folder of your System Folder. They can be easily accessed throuh an alias in the AppleShare IP 6.2 folder, or from the Help menu within AppleShare Web and File Admin.

Mac OS X Server 1.x: Dual Startup Loses Monitor Preferences

When starting up your computer running Mac OS 8.6, and then restart using Mac OS X Server 1.x, the monitor comes up in 640 x 480 resolution.

This article has been archived and is no longer updated by Apple.

When the computer is started up using Mac OS 8.6 and then restarted using Mac OS X Server 1.x, the monitor preferences are lost. The administrator (root) must log in and reset the preferences using the Monitor preferences from the Apple Menu, or the Preferences application. The only workaround for this issue is to use the MacOS.app instead of dual startup.

Differences Between Rage Pro and Rage Pro Turbo Chipset

This article describes the differences between the ATI Rage Pro graphics chipset and the ATI Rage Pro Turbo graphics chipset used in Macintosh computers.

This article has been archived and is no longer updated by Apple.

Both are equal in functionality and performance. There are a few very minor differences between the two chips but they affect only those computers that include support for the AGP (Accelerated Graphics Port) architecture. Since the Macintosh computers in which these chips were included do not support the AGP architecture, they are not affected by these minor changes.

Mac OS X Server 1.x: Installation on ATA/IDE Slave Drives

Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Mac OS X Server cannot be run from, nor installed upon, any ATA/IDE Slave device. Attempts to install Mac OS X Server on, or run it from, a slave ATA/IDE device will fail, or return error messages.

1. When I open the Mac OS X Server installer and select my hard disk target partition for installation, it looks like everything works, but when it finishes, I get an error message that reads something like:

> Mac OS X Server Installer had problems setting startup to the Mac OS X Server CD
>
> [Sorry] button (no cancel or OK)

If I click Sorry, I get a new dialog with a restart button, but the computer starts up back to Mac OS. What could be wrong?

2. After running the Mac OS X Server installer, the system failed to restart from the Mac OS X Server UFS partition of the installation disc. It came up in Mac OS instead. When I open the System Disk control panel (an application provided on the Mac OS X Server installation disc), I don't see the disc among the choices of partitions. I see only "Power User - NVRAM" and the other Mac OS and Mac OS Extended format partitions on my hard drive(s). The disc is available, and the Mac OS partition on it shows up on the desktop. What could be wrong?
This article has been archived and is no longer updated by Apple.
ATA/IDE drives must be configured (usually with a jumper) as IDE Master devices to start up with Mac OS X Server. Thus, the target partition for an installation must be on an IDE Master device, and so must the Mac OS X Server partition of the Installer disc, so that the installer can properly configure Open Firmware to recognize that partition as the startup partition.

The System Disk control panel prevents installation on slave devices by displaying only partitions that reside on ATA/IDE Master drives (or any SCSI volume).

The error message about being unable to configure the Mac OS X Server partition of your disc as the startup device that you received is one of the few hints as to the nature of the difficulty. Because Mac OS X Server cannot start up from an ATA/IDE Slave device, the error is encountered as the installer attempts to save an incompatible configuration.

Typically, only users who have added slave devices, or otherwise altered their IDE configuration will encounter this sort of difficulty.

Standard factory and almost all build-to-order configurations of Power Macintosh G3 (both Blue and White and Platinum) computers will accept installation without complaint. Platinum Power Macintosh G3 computers came in several configurations: all SCSI, SCSI drive and IDE CD, and both IDE. The Blue and White G3 computers have IDE CD and hard disk drives, both masters, but on separate IDE channels, server configurations and some BTO workstation systems may have factory-equipped SCSI cards and SCSI hard disks.

Notes:

1. Only Apple factory-shipped SCSI cards are compatible with Mac OS X Server at this time. Additional SCSI support for versions of SCSI cards other than those shipped in preconfigured systems by Apple will not accept installation of Mac OS X Server, and will not be available from within the Mac OS X Server environment, until the manufacturers of those cards release Mac OS X Server-compatible drivers. The Apple OEM versions of these SCSI cards are NOT identical to those offered by the original manufacturers, and Apple's drivers are not interoperable with non-Apple versions of these cards.
2. Once the Installer has been run on the target partition, the target partition will no longer appear in the System Disk control panel application window, as it has been made an intermediate volume type. Completing the installation successfully will change it to a UFS partition, at which point it again becomes available from within the System Disk control panel application.

Mac OS X Server 1.x: Can‘t Change File Name Case on Mac OS Extendend Format Volume

I am trying to change the name of a file so that the capitalization is different. However, when I try to change "document" to "Document", the Workspace Manager gives me the error "Name already in use: document."
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001. This is not an issue in Mac OS X Server 10.0.3 and later.

This issue affects files and folders on Mac OS Extended format volumes (HFS Plus). It does not affect UFS format volumes.

To work around this issue, give the file an intermediate name.

For example, to change a filename 'foo' to 'Foo' do the following:

foo -> bar -> Foo
Published Date: Feb 18, 2012

MacX 2.0: Extensions Required by MacX 2.0.4 X11 Display Server

MacX 2.0 requires several extensions, included with the software disc. These are:

- XIE.shl: provides support for certain X11 graphics standards (XIE)
- NetManage Winsock Lib: provides mapping to Mac OS TCP/IP APIs
- PacerFTP: provides support for FTP file transfers from within MacX

This article has been archived and is no longer updated by Apple.
The most common issues arise when MacX is drag-copied, and one or all of these extensions is overlooked. MacX should be installed from the original media, or care should be taken otherwise to ensure that all three of these extensions are installed in the active System Folder before MacX is used.

Macintosh Portable Data Modem 2400: Dialing Without Dial Tone

We have had reports that the Macintosh Portable Data Modem 2400 cannot find a dial tone when plugged into an internal switchboard. The Hayes commands to do this, although accepted by the modem, seem to have no effect.

This article has been archived and is no longer updated by Apple.
Setting the active result codes with the X command tells the modem to:
- dial after a delay set by modem register S6, and
- not wait for a dial tone.

Use the following commands. You may or may not need to set register S6, depending on the phone system in use. The text in parentheses is comment only, and not part of the commands.

ATX3 (OK, CONNECT, RING, NO CARRIER, ERROR, CONNECT 1200 & 2400, BUSY)
ATS6=3 (Wait 3 seconds. Default is 2, so this probably isn't necessary.)

iBook: Video Memory Not Upgradeable

How much VRAM is in iBook and is it expandable?

This article has been archived and is no longer updated by Apple.

iBook uses the ATI RAGE Mobility video controller for 2D and 3D graphics acceleration. The chip comes standard with 4 megabytes of video memory. Because the video memory is embedded in the ATI RAGE Mobility chip, it cannot be upgraded. However, 4 megabytes of SDRAM is sufficient for supporting millions of colors on the internal iBook display.

Apple IIGS: Disabling the Control Panel

How can I disable the Control Panel on the Apple IIGS?

This article has been archived and is no longer updated by Apple.
The following is Electronic Learning Systems' description of Menu Master, a product that provides a way to disable the Apple IIGS Control Panel. For further information on ELS, search the Technical Information Library on "ELS".

"Menu Master is a simple menu system for the Apple II. It allows creation of customized menus and sub-menus to launch all ProDOS, GS/OS, and DOS 3.3 applications. Menu Master provides automatic pathfinding, simplifying the need to understand or manually set ProDOS paths. Menu Master has password protection, is mouse-compatible, and displays the time and date from any ProDOS clock. A utility feature enables or disables the Apple IIGS Control Panel.

"DOS 3.3 programs can now be launched and returned from, within the ProDOS operating system. DOS 3.3 software developers now have the ability to run DOS 3.3 programs on AppleShare or any ProDOS-specific environment.

"Any Apple II with 128K of memory and an 80-column display can now organize, launch and return from ProDOS, GS/OS, and DOS 3.3 applications with Menu Master. Apple IIc Plus systems can have 3.5-inch diskettes created with DOS 3.3 programs that will run on their computers.

"The network version of Menu Master is compatible with all Apple II networks including AppleShare, Corvus, ELAN, VELAN, and DIGICARD. Menu Master provides all the features of Apple's Aristotle program when used on AppleShare, but requires no memory expansion and can launch DOS 3.3 applications."

Mac OS 8.5: Installing on a Disk Larger Than 21 Gigabytes

I've noticed that I cannot install Mac OS 8.5 and other software using an Apple Installer (such as AppleShare IP 6.1) on a volume larger than 21 Gigabytes.

This article has been archived and is no longer updated by Apple.

The installer version accompanying Mac OS 8.5 and AppleShare IP 6.1 does not properly deal with volumes larger than 21 Gigabytes. The version of the installer application that accompanies Mac OS 8.6 corrects this limitation. If the newer version of the installer is not available, partitioning the drive so that a smaller than 21 Gigabyte segment is available will allow the older installer to function.

TA44368_Personal_LaserWriter_Multiple_Port_Switching__(TIL06045).pdf

Personal LaserWriter: Multiple Port Switching (11/94)

Is it possible for a Personal LaserWriter to switch printing sessions between the serial port and the LocalTalk connection without the user having to use the hard switch? The customer wants one printer that will work in both environments and is "smart" enough to spool documents from one side while printing on the other.

This article has been archived and is no longer updated by Apple.
The Personal LaserWriter NT was not designed with the necessary intelligence to handle print jobs from both ports simultaneously. This would require an internal spooler that could queue print jobs from either port. It would probably also need to handle switching between PostScript and different emulations on the fly for this to be useful. You have two possible solutions: an external switching device or a different printer.

One such external device is a third-party product called BridgePort, by Extended Systems Inc. BridgePort lets any PostScript printer (including all of Apple's) accept jobs from a serial, parallel, or LocalTalk port. This external device automatically switches input to either a serial or parallel output to the PostScript printer. It is limited to accepting PostScript jobs only; it can't switch between HP and PostScript.

The LaserWriter Pro printers from Apple are capable of accepting print jobs from different ports without any additional hardware or software switching.

iBook: Secure By Running Cable Through Handle

This article explains how to secure an iBook computer by running a security cable through its handle.
This article has been archived and is no longer updated by Apple.
iBook and iBook (FireWire) computers do not have a security slot.

To secure an iBook computer, in a classroom, for example:

1. Run a security cable through the iBook computer's handle. Almost any security cable system that works with an iMac computer will work with an iBook computer.
2. Secure the security cable to a fixed object or surface.

Note: The iBook (Dual USB), iBook (Late 2001), and iBook (14.1 LCD) computers all have a security slot.

Mac OS 9: Multiple Users - Non-Admin Users Can Create Alert Sounds In System File

New alert sounds are being added to the System, even though I only have panels and limited users defined. Is this a security hole in Multiple Users?

This article has been archived and is no longer updated by Apple.

Even though Limited and Panels user accounts are prevented from modifying the System file directly, those users can use SimpleSound to add alert sounds to the System file of System Folder. This is the nature of the way SimpleSound works. If you wish to limit Non-Admin users from adding alert sounds, then you should deny users access to SimpleSound.

Sounds recorded with the SimpleSound application will not be accessible to users in the Limited and Panels environments. These sounds are stored in the System file, which Limited and Panels users are not allowed to open.

These new alert sounds will appear in the Sound Control Panel and may be selected as alert sounds by Limited and Panels users.

AppleShare File Server: How To Set Unattended Restart

A customer needs to perform daily unattended restart of several Macintosh systems that are used customer as communications servers.

This article has been archived and is no longer updated by Apple.
CE Software's QuicKeys and QuickTimer CDEVs should provide the solution.

QuickTimer can run a QuicKeys sequence called "Daily" at a specified time every day, or run a sequence called "Periodic" at regular intervals. From Finder or MultiFinder, define a QuicKeys sequence that does a Restart, and name it "Daily". The sequence needs a keyboard equivalent to be called by QuickTimer. Set the time you want the "Daily" sequence to be run, and restart the computer. The system should restart every day at the time specified in QuickTimer.

If the Macintosh Systems are AppleShare File Servers

In this case, the setup is a little more complicated. There are six steps: patch the AppleShare file server software (please note that this patch is an unsupported solution), define four QuicKeys sequences, and use the Control Panel to choose a time.

Note: It's not necessary to patch AppleShare if the file server is a Macintosh IIcx or Macintosh IIci, because you can lock the power switch in the ON position on these systems. With the power switch locked in the ON position, the Macintosh IIcx and Macintosh IIci automatically restart after the Shut Down command is issued. This is not possible with Macintosh II and Macintosh IIx, because their power switches don't lock in the ON position.

Step A

When Shut Down... is selected from the Server menu, the AppleShare file server closes all open files, writes information in the disk cache to disk, and shuts down the system. You need to patch the AppleShare file server software to just Restart instead of Shut Down.

The Shutdown Manager procedure is called ShutDwnPower, and it turns the computer off. If the Macintosh must be turned off manually (for example, a Macintosh SE), the Shutdown alert is presented to the user.

Disassembled, ShutDwnPower looks like this:

MOVE.W #1,-(SP) ;1 is the selector for the "ShutDwnPower" proc
_Shutdown

and in hexadecimal:

3F3C 0001 A895.

You need to have AppleShare call ShutDwnStart (the Shutdown Manager) instead of ShutDwnPower. ShutDwnStart restarts the system instead of turning it off.

Disassembled, ShutDwnStart looks like this:

MOVE.W #2,-(SP) ;2 is the selector for the "ShutDwnStart" proc
_Shutdown

and in hexadecimal:

3F3C 0002 A895.

Here's how to use ResEdit to make this change:
1) In ResEdit, open the application AppleShare File Srv (in the "Server Folder").
2) Open the CODE resources, find the 2 "Main" ID = 1 resource, and open it.
3) Select Find Offset... from ResEdit's Find menu.
4) Enter an offset of "512D" (a hexadecimal number).
5) "01" is highlighted in the CODE "Main" ID = 1 window. Type "02".
6) Select Save from ResEdit's File menu, and quit.

Here's how to apply the same patch using a file editor such as FEdit:
1) Use the file editor to open the application named AppleShare File Srv.
2) Search for the hexadecimal string "3F3C 0001 A895" (this occurs only once).
3) Replace the string with "3F3C 0002 A895".
4) Save the changes.

Now, the AppleShare file server will restart instead of shutting down when Shut Down... is selected from the Server menu.

(For more information on the Shutdown Manager, see pages 585 to 590 of Inside Macintosh Volume V.)

Step B

Define a QuicKeys sequence that issues a Shut Down command:
1) With the AppleShare file server running, select QuicKeys from the Control Panel.
2) From the QuicKeys CDEV's Define menu, select Menu/DA....
3) From AppleShare's Server menu, select Shut Down.
4) Give this QuicKeys sequence a unique keyboard equivalent, perhaps Shift-Control-A.

Step C

Define a QuicKeys sequence that enters the "Number of minutes until shutdown" into the time delay dialog:
1) From the QuicKeys CDEV's Define menu, select Text....
2) Type the number of minutes you want the AppleShare file server to delay before shutting down.
3) Give this QuicKeys sequence a unique keyboard equivalent, such as Shift-Control-B.

Step D

Define a QuicKeys sequence that selects the OK button in the dialog:
1) From the QuicKeys CDEV's Define menu, select Buttons...
2) When a dialog asks you to "Enter button to look for", type "OK" and click on the OK button.
3) Give this QuicKeys sequence a unique keyboard equivalent, such as Shift-Control-C.

Step E

Define a QuicKeys sequence that links all the above sequences:
1) From the QuicKeys CDEV's Define menu, select Sequences...
2) A dialog appears; on its right side are the three QuicKeys you already defined. On the left side is the default name "List". Change that name to "Daily".
3) Double-click the QuicKeys on the right side of the dialog in this order:
- Shift-Control-A Shut Down...
- Shift-Control-B '5'
- Shift-Control-C OK
4) Click the "OK" button.
5) Give the "Daily" sequence a keyboard equivalent.

6) In the Control Panel, select the QuickTimer CDEV.
7) Click the word "Daily" so that the check box is selected, and set the time.

Step F
---
1) From the Control Panel, Select the QuickTimer CDEV.
2) Click on the word "Daily", so that the check box is selected.
3) Set the time to, say, 4:30 am.

The AppleShare file server will now shut down and restart every day at the defined time.

Videodisc Control Stacks for CLV and CAV Formats

Does the APDA Videodisc Toolkit, which allows you to control a videodisc player from HyperCard, work with both CAV and CLV discs?

This article has been archived and is no longer updated by Apple.

The command set of the videodisc player is the same for both CAV and CLV discs. This means that the Videodisc Toolkit will work with both type of discs.

However, there are differences in the discs that will not allow certain commands to provide useful results. Because the Videodisc Toolkit documentation states that the Toolkit does not specifically address CLV control, determining the controls that actually work with CLV discs is a matter of exploring. (Often, the videodisc player determines the available functions when using CLV discs. The player knows whether a CLV or CAV disc is loaded. Some functions are disabled by the player when CLV discs are in the tray.

Commands related to "frameMode" -- that is, "videoFrame()" -- do not work. Using "chapterMode" instead allows access to longer sections of video. The "playVideo" and "searchVideo" commands use chapter numbers rather than frame numbers when in "chapterMode".

Still-frame with CAV discs provides a crisp and clear still image. Attempting to freeze a frame from a CLV disc will not produce a stable image. This is a limitation inherent in the design and layout of CLV discs, not a limitation of the Videodisc Toolkit. CAV discs place one video frame per revolution of the disc; CLV discs place any number of frames within one revolution. One frame per revolution allows the disc to continue to spin with the laser reading head stationary, thus providing the same frame once per revolution. CAV discs have differing numbers of frames from the outside edge of the disc to the inside of the disc. Holding the

laser reading head stationary will not provide a stable image, because there is a variable number of frames/fields passing under the head in one revolution.

The Voyager Company markets "The Voyager VideoStack", which supports time mode with the CLV discs. This allows a stack to tell the player to go, for example, to "19 minutes 12 seconds" and begin playing until it reaches "21 minutes 32 seconds." This is not frame accurate, but in many situations provides sufficiently accurate control.

Voyager also provides "VideoStack 8000 Extension", which is for the Pioneer 8000 player. These extensions support special 8000 model features, such as true CLV still-frame and CLV frame search, digital sound control, and still-frame with audio. CLV still-frame is achieved through the use of the Pioneer 8000 digital frame buffer. The Pioneer 8000 can search to a particular frame and grab a frame of video into its digital buffer. This is different from the CAV method of still-frame.

The Tech Info Library article titled "Locating Vendor Information" can help you search for a particular vendor's address and phone number.

Mac OS X Server 1.x: Managing NFS Exports

The icon for adding an NFS export directory is dimmed in the NetworkManager's File Sharing application. How can I manage NFS exports?
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Here are two ways to manually manage NFS exports without running NetworkManager. Both involve directly storing values into the /exports directory of your local NetInfo database.

Managing NFS Exports With NetInfoManager.app

1. Start the NetInfoManager.app application. It will open up the local NetInfo database; you can verify this by looking at the title of the window--it should start with "local@ yourhostname..."
2. In the directory browser area, click on the exports directory. This should display the current exports, if any, in the rightmost column.
3. To add a new export, select the "New Subdirectory" command under the Directory menu. It will create a directory named "`new_directory`". You may be prompted for root password here.
4. Rename the "`new_directory`" to the path of the UFS directory you want to export. To do this, double-click on the "Value(s)" field corresponding to the "name" property, and type in the new path.
5. Add a "clients" property. To do this, select an existing property and select the "New Property" command under the Directory menu. Give it a name of "clients", and give it a name of "clients", and give it a list of values of client machine you want to export the directory to by selecting the "New value" from the Directory menu.
6. Add an "opts" property. For details on the values, see the man page for exports(5).
7. Do a save from NetinfoManager.app.
8. Restart the server. (Alternatively, if you feel lucky, use Terminal.app to start 'mountd' if it's not running, or send it a SIGHUP if it is by typing the following command: `kill -HUP `cat /var/run/mountd.pid`

Managing NFS Exports using nidump/niload

To manually add a new exported directory, you can use the 'nidump' and 'niload' command line utilities as follows:

1. Start the Terminal application; all this will be done as root.

2. Dump the existing exports, if any, to a file. Start the Terminal application. Type the following commands at the prompt:

```
su root
nidump -r /exports . > ~/exportfile
```

Note that the '.' indicates the current domain.

This places a list of all the existing exports in a file, using a property-list notation.

3. Edit the file to add new exports or modify existing exports.

```
cp ~/exportfile ~/exportfile.bkup
open ~/exportfile
```

At this point, TextEdit should launch, and you can add or modify exports, and save. A typical file with two exports might look like this:

```
{
 "name" = ( "exports" );
 CHILDREN = (
   {
     "clients" = ( "17.221.1.2", "hosta", "hostb" );
     "name" = ( "/exportdir1" );
     "opts" = ( "maproot=root" );
   },
   {
     "clients" = ( "17.221.1.2", "hosta", "hostb" );
     "name" = ( "/exportdir2" );
     "opts" = ( "ro", "maproot=root" );
   }
 )
}
```

4. Load the modified exports back into Netinfo.

```
niload -r /exports . < ~/exportfile
```

5. If something goes drastically wrong, restore the original exports:

```
niload -r /exports . < ~/exportfile.bkup
```

6. Restart the server. (Alternatively, if you feel lucky, use Terminal.app to start 'mountd' if it's not running, or send it a SIGHUP if it is by typing the following command:

```
kill -HUP `cat /var/run/mountd.pid
```

ALAC (Any Language, Any Computer) Product Information

Is there a programming environment that allows programmers to use one language to write a host application that controls systems as diverse as Macintosh, IBM mainframes, DEC VAX, Cray, and IBM PCs?

This article has been archived and is no longer updated by Apple.
United Data Corporation has announced a product that facilitates this process: ALAC (Any Language, Any Computer).

ALAC is a MacWorkStation-compliant MS-DOS application server that runs under MS Windows. A PC running ALAC responds to the same protocol messages as a Macintosh running MacWorkStation. This lets you build applications while your users remain on familiar hardware. You can use COBOL, Fortran, C, BASIC, or APL. Any computer that can run Windows can also run ALAC.

ALAC provides access to a graphical user interface. Programmers not familiar with Windows and the Macintosh can build applications for these environments, with full access to and control of dialog boxes, menus, and windows.

Single-user versions of ALAC are available through United Data or through APDA. Site licenses are available through United Data. For further information on United Data Corporation or APDA, search the Tech Info Library for the name.

iMovie: About Shelf Spaces Available With Different Resolutions

This document describes the shelf spaces available at different monitor resolutions.
This article has been archived and is no longer updated by Apple.
iMovie 1 and 2 were designed to work best in 1024- by 768-pixel resolution, in thousands or millions of colors.

iMovie 3 requires a 1024- by 768-pixel resolution, or higher, to open.

Most consumer Macintosh computers offer four monitor resolutions: 640 by 480, 800 by 600, 832 by 624 and 1024 by 768. iMovie will not open with the resolution set to 640 by 480 pixels.

When using iMovie 1 or 2 in 800 by 600 and 832 by 624 resolutions, the Shelf has nine Shelf Spaces. In 1024 by 768 resolution there are 12 Shelf Spaces.

When capturing clips from your camera onto the Shelf, iMovie will automatically create a separate clip and put it into a new Shelf Space every time a scene break is detected. In earlier versions of iMovie, these Shelf Spaces may fill up quickly depending on the number of times you stopped and started recording when you initially shot your source footage. In iMovie 2 and later, Shelf space will expand dynamically, allowing you to scroll through the shelf space as it fills. To avoid filling up all Shelf Space in iMovie 1, which disables further capturing until space is cleared, there are a few options:

- Open the application Preferences and click the Import Tab. Here you can select the destination of the imported clips. By selecting to import clips directly to the timeline, you can avoid filling the Shelf with newly captured clips.
- Deselect the checkbox "Automatically start new clip at scene break."

iMovie 1.0: Speed of Movie Seems to Slow Down During Cross Dissolves

If you use a cross dissolve in iMovie 1.0, you may notice that the motion seems to slow down during the dissolve, then return to normal speed when the dissolve is complete.
This article has been archived and is no longer updated by Apple.

Symptom

When you playback a movie with cross dissolves, the motion seems to slow down during the dissolve, then returns to normal speed when the dissolve is complete.

Solution

Download and install iMovie 1.0.2 update, which is available from http://download.info.apple.com/ .

In iMovie 1.0, when you select Cross Dissolve from the Transition Palette, there will be a slight decrease in speed for the footage to which the cross-dissolve is applied. With the time slider in the Transition Palette, you can determine how long the dissolve will be.

The Cross Dissolve transition in iMovie 1.0 was designed to maintain the overall length of the sequence, so that transitions applied at the beginning of a movie don't affect any synchronization of audio and video you may have done at other points in the timeline after the transition.

Users have requested the ability to have the option of using both slow- and normal-speed Cross Dissolves. This feature is incorporated into iMovie 1.0.1 and later.

HyperCard and Multi-User Applications on Servers

Some customers have reported problems using HyperCard to open multi-user applications that are on a server. If they launch the application from a HyperCard script, they don't have multi-user access.

If they launch the application from the Finder, then use the HyperCard script to open a session with the application, they do have multi-user access. And if they launch the application entirely without HyperCard, they have multi-user access.

This article has been archived and is no longer updated by Apple.
When you launch an application using HyperCard's Open command, it opens the application with privileges that lock the file. This prevents any other application, including the Finder, from launching the same application. HyperCard's Open command, therefore, can not multi-launch a single application.

There are ways to work around this. As mentioned, if you initially launch the application from the Finder, additional launches of the application from HyperCard do work, because it's the first application (in this case, the Finder) rather than HyperCard that sets the privileges of the open file.

You can also write an XCMD that does what the Open command does, except that you set the privileges for multilaunch in the XCMD.

Another option is to launch multi-user applications locally, rather than from the server. We've found that multi-user applications work faster when each Macintosh has a local copy of the application and accesses only the data file on the server. If the application is kept at the root level of each Macintosh, a HyperCard stack could launch the application locally, and the application could get the data from the server.

If you don't want to have the application at the root level, you can:
- program each HyperCard stack with the access path to the application; or
- have the user tell HyperCard where the application is on the local disk (via the dialog that HyperCard shows if it doesn't know where an application is).

Mac OS 9: AppleShare 4.0.2 Drop Boxes

This article provides important information about Mac OS 9 and AppleShare 4.0.2 drop box.
This article has been archived and is no longer updated by Apple.
With Mac OS 9, you cannot copy files to drop boxes located on AppleShare 4.0.2 servers. This issue does not occur with newer versions of AppleShare.
Published Date: Feb 18, 2012

Mac OS 9: Apple LaserWriter 8f Printer Driver Not Compatible

As reported in Mac OS 9 Late Breaking News, the Apple LaserWriter 8f printer driver is not compatible with Mac OS 9. If you have this driver installed, remove it and use the LaserWriter 8 driver instead.
This article has been archived and is no longer updated by Apple.
PostScript Fax is an option for the LaserWriter Select 360, the LaserWriter 16/600 PS, and the LaserWriter Pro 810. Apple discontinued PostScript Fax printer driver development many years ago and the last PostScript Fax driver created was LaserWriter 8f (v8.2.3). Though these printers can continue to receive faxes and you can print to these printers, sending faxes with old drivers is not supported with Mac OS 9.

LaserWriter 8, version 8.7 supports PostScript output filters, which are code fragments that live in the data fork of files that reside within the "Printing Plug-ins" folder contained in the Extensions folder. These code fragments can intercept the PostScript output data stream generated by LaserWriter 8 and add, remove, or modify the data before it is transmitted to the output device. Such a filter could add PostScript fax instructions to a "print job," and should such a third party PostScript fax output filter become known to Apple, the information will be posted here.

LaserWriter 8.3.4 has limited PostScript fax capabilities, and though no compatibility testing was performed with it and Mac OS 9, Apple was able to send faxes successfully with this driver. Again this was not tested, nor is this solution supported. Should you wish to experiment with this potential solution, the driver may be downloaded from Apple Software Updates. Place the driver in the Extensions folder or drag it onto your System Folder, then select your printer using this driver via Chooser. Mac OS 9's printer PPD files may be used with this old driver. LaserWriter 8.3.4 requires you to enter your fax destination; LW 8.3.4 will remember the last phone number you faxed to, so if you wish to fax to a different destination you'll need to enter the new number. It has no support for the Fax Phone Book, LaserWriter Fax Log, or the Fax Printer Utility.

Important: After sending a 'fax' using the LW 8.3.4 driver, Apple strongly recommends you reselect and use the LaserWriter 8, version 8.7 to 'print' to these printers.

Data Access Language: Problem Opening Rdb Databases

A customer had a problem with DAL that prevents Rdb/VMS databases from being opened in certain cases. When they issue the OPEN DATABASE command

OPEN RDB DATABASE 'mydisk:[mydir.mysubdir]my_database'

the database can't be opened.

This article has been archived and is no longer updated by Apple.
You always need to use the IN LOCATION or USE LOCATION statement to open databases that are not in the default directory. Although you might have been able to open databases by specifying the full path name with the database name in version 1.0, later versions (which support opening multiple databases simultaneously in Rdb) do not accept a full path name here.

Mac OS 9: Requires AppleShare Client 3.8.5 Or Later

Mac OS 9.0 includes AppleShare Client 3.6.5 in the Utilities folder on the Mac OS 9.0 Install disc. I copied this version into my System Folder and now I have problems connecting to AppleShare servers.
This article has been archived and is no longer updated by Apple.
Mac OS 9 requires AppleShare Client 3.8.5 or later. This is the version of the AppleShare Client that is installed with Mac OS 9.0. Do not use earlier versions of the AppleShare Client with Mac OS 9.

AppleShare Client 3.6.5 is only provided on the Mac OS 9.0 Install disc for customers with an AppleShare Client version earlier than verson 3.6.5 who wish to perform a network install of Mac OS 9.0. Customers with a newer version of AppleShare Client should not replace it with AppleShare Client 3.6.5.

QuickFile III: String overflow error

This article has been archived and is no longer updated by Apple.
When you try to save your file, QuickFile III prompts you for the date for the catalog. If you type in eight or more characters, which is more than QuickFile can convert to a valid date, the program stops with a String Overflow error and loses all the data you just typed in.

To avoid this error, verify that the date you typed in is correct before pressing RETURN. Examples of what QuickFile considers to be valid dates are listed on page 41 of the QuickFile Manual.

AppleShare IP 6.3: Using AppleShare IP First Aid

This article provides troubleshooting information for AppleShare IP 6.3.
This article has been archived and is no longer updated by Apple.

Opening AppleShare IP First Aid

Before you can open AppleShare IP First Aid, you must restart the server computer with extensions turned off. Be sure that no one is connected to the server, or notify any connected users that they will be disconnected.

To open AppleShare IP First Aid:

1. Press the Shift key and choose Restart from the Special menu. The computer starts up with extensions turned off.
2. Open the AppleShare IP 6.3 folder on your server's hard disk.
3. Open the AppleShare IP First Aid folder.
4. Double-click the AppleShare IP First Aid icon.

Backing up AppleShare IP PDS and data files

PDS files are invisible files that store information about privileges, shared items, and other AppleShare IP information.

To back up AppleShare IP PDS and data files:

1. With AppleShare IP First Aid open, click Backup.
2. Choose the volume you want to back up.
3. Type a name for the backup file and click the Backup button.

The backup file is saved in the AppleShare IP 6.3 folder.

Verifying or reconstructing PDS files

To verify or reconstruct AppleShare IP PDS and data files:

1. With AppleShare IP First Aid open, click Verify PDS or Reconstruct PDS.
2. Select the volume that contains your AppleShare IP server software.
3. Click Choose.

The results appear in the AppleShare IP First Aid window.

Verifying or reconstructing Users & Groups data

To verify or reconstruct Users & Groups data:

1. With AppleShare IP First Aid open, click Verify UG or Reconstruct UG.
2. Select the Users & Groups Data File you want to verify or reconstruct.
3. Click Verify or Reconstruct.

The results appear in the AppleShare IP First Aid window.

AppleShare IP 6.3: Setting Up The Filter List

This article explains how to set up a TCP filtering list for AppleShare IP 6.3.
This article has been archived and is no longer updated by Apple.
The default filter list blocks all access to your server. You can change the filter list by adding, changing, duplicating, or deleting filters.

Note: If you add or change a filter after turning on TCP filtering, it does not affect connections already established with the server. For example, if you deny all access to your Web site, computers already connected to your Web site are not disconnected.

To edit the filter list:

1. Open the Apple menu and choose AppleShare IP Admin, then choose TCP Filter Admin from the submenu.
2. Click the Add button, or select a filter and click the Edit, Duplicate, or Delete button. If you are deleting a filter, you're finished. Otherwise continue with step 3.
3. Select the type of access (Allow or Deny).
4. Select a port by typing the number in the Ports box or choosing it from the pop-up menu.
5. Type an IP address or range in the box, or click Find and enter a domain name.

If you click Find, the search returns one IP address in that domain. You can then use asterisks to define a range of addresses based on the sample address.

If an IP address search is taking a long time:
You may have entered an invalid domain name, or the network may be busy. Check the name and try again.

AppleShare IP 6.3: Users Can‘t Search the Web Site With Sherlock

This article provides troubleshooting information for AppleShare IP 6.3.
This article has been archived and is no longer updated by Apple.

- Make sure you've created an index for the volume on which the Web folder is located.
- Check to be sure the Sherlock plug-in is in the Plug-Ins folder in your server's Web folder.
- Try fixing volume creation dates.
    1. Open AppleShare IP Advanced Setup (located in the Web & File Server folder in the AppleShare IP folder on your server.
    2. In the Server menu, choose Fix Volume Creation Dates.

iMovie: Setting Resolution to 640 by 480 Forces Application to Quit

When you change the display resolution to 640 by 480, iMovie quits.
This article has been archived and is no longer updated by Apple.

Symptom

When you change the display resolution to 640 by 480, iMovie quits.

Figure 1 iMovie alert

Solution

To get back to your project:

1. Change the resolution back to 800 by 600 or higher.
2. Open iMovie again.

iMovie is designed to work at 800- by 600-pixel resolutions, or higher. It will not work at 640 by 480. While a movie is being edited iMovie will warn you not to select the 640 by 480 resolution. Changing the resolution to 640 by 480 automatically forces the application to quit. If any edits have not been saved, you will be offered the opportunity to save any changes.

Mac OS 9: Installation Space Calculated For Standard Format Is Too Low

I could not install Mac OS 9 due to lack of disk space even though the Installer claimed there was more space available than it would need before it started.
This article has been archived and is no longer updated by Apple.
The space required for Mac OS 9 may be higher than the Installer indicates if the disk you're installing on is formatted as a Mac OS Standard format (HFS) volume. To reduce the chance of the installation not completing, you should free up an additional 25 megabytes of disk space.

If your disk or volume is larger than 1 gigabyte, you should consider backing up the files and programs stored on it, and reformatting it as a Mac OS Extended format disk or volume using the Drive Setup utility. After reformatting you can restore your files and programs from you back up. This will provide considerable additional free space for future use.

LaserWriter: Using Refilled Toner Cartridges

This article has been archived and is no longer updated by Apple.
Apple does not recommend the use of refilled toner cartridges because print quality may suffer as parts inside the toner cartridge wear out. Using refilled toner cartridges in your LaserWriter, LaserWriter Plus, LaserWriter II, or Personal LaserWriter printers may or may not cause damage. The impact on Apple printers is difficult to assess because it is impossible to predict the quality of refurbished cartridges.

The use of a refilled toner cartridge in your printer will not void a LaserWriter printer's limited warranty or an AppleCare contract. However, if printer failure is attributable to the use of a refilled toner cartridge, the damage resulting from this failure will not be covered under Apple's limited warranty or AppleCare contract.

The following is a reminder of which cartridges to use with your printer:
- The LaserWriter and LaserWriter Plus both use EP cartridges.
- The LaserWriter II uses EPS cartridges.
- The Personal LaserWriter uses EP-L cartridges.

Mac OS 9: What‘s New - Notification Manager Alerts

The Notification Manager is a part of the system software that Apple and non-Apple programs use to notify users of some kinds of events. One way to notify users is by using an alert box. Mac OS 9 uses different alert boxes than previous versions of the Mac OS.
This article has been archived and is no longer updated by Apple.
Starting with Mac OS 9, Notification Manager alerts look and act a little differently than under previous versions of the Mac OS. The new alerts are modeless, so the computer keeps working whether or not you dismiss the dialog. Also, the alerts are smaller, rectangular and have a yellow background. The window has a close box and collapse bar instead of an OK button.

Figure 1, Mac OS 9 Notification Manager alert

Wherever you reposition the alert window, that's where it will show up again the next time you get an alert.

Multiple notification windows will not show up at the same time. You have to dismiss the first notification to get the next notification in line. For example, if you disconnect and then reconnect your AppleTalk connection, you will first get an alert that your connection was disconnected, then once you close that window, you'll get the subsequent notification that it is now available.

iMovie: About Saving DV Video to European Cameras

Digital video (DV) cameras sold in the European Union may not allow you to save movies from your Mac to your camera.
This article has been archived and is no longer updated by Apple.
Due to European Union import restrictions the DV-in feature, or ability to save DV movies to a camera, is disabled on most consumer-level digital video cameras sold in Europe. This feature is only enabled on certain high-level consumer and professional camera models. When this feature is enabled on a camera, it will work fine with iMovie.

While iMovie does have the ability to save out to a digital video camera, it can only do so on camera models that allow this feature to work. It's important to remember that if you are not able to save DV videos to your camera it is a limitation of the camera and not the iMovie application.

You may want to contact the store where you bought your camera, or the camera's manufacturer to determine what steps you can take to record movies from iMovie to your camera.

Mac OS 9: Audio CDs Always Play Through On Some Computers

I have two computers with Mac OS 9 installed. When playing Audio CDs on them, one plays through regardless of the setting in the Sound control panel. The other only plays through when "Internal CD" is selected as the input source in the Sound control panel. How do you fix this for them?
This article has been archived and is no longer updated by Apple.
This is expected behavior under Mac OS 9. Computers with SCSI CD-ROM drives and ATAPI drives (except ROM-in-RAM computers) play through only when "Internal CD" is selected as the sound input source. Computers with ROM-in-RAM and ATAPI CD ROM drives play through regardless of the sound input source selected in the Sound control panel.

ROM-in-RAM computers are iMac, iBook, PowerBook (Bronze Keyboard and later PowerBook models), Power Macintosh G3 (Blue & White model only), All Power Mac G4 computer models. These are also the computers that happen to have USB built-in.

LaserWriter IINTX: How To Network a PS/2 and Macintosh Computers

You can connect multiple IBM PS/2 computers, Macintosh computers, and one Apple LaserWriter IINTX, so that all the computers are connected to the LaserWriter and using it simultaneously.

This article has been archived and is no longer updated by Apple.

DayStar Digital Solution

The best solution is to use a LocalTalk MicroChannel card. The MicroChannel systems can be networked together using a AppleTalk card for the MicroChannel bus PS/2s by DayStar Digital (the LT200MC MicroChannel LocalTalk card). The card lets MicroChannel PS/2s communicate with other AppleTalk system components, like the LaserWriter IINT/NTX. The card comes with software for PS/2s to connect to AppleTalk printers, like LaserWriters. TOPS is reported to work with the card, too. AppleShare PC is reported to be incompatible with the DayStar card. For more details, search the Tech Info Library under "Day Star".

3COM Solution

Another solution is to use the EtherLink MC PS/2 card from 3COM. This is a more complex solution, because it involves several components. This connects MicroChannel PS/2s to Ethernet. The PS/2s can print to a 3S200 server from 3COM and connect to a serially-connected LaserWriter II. The Macintoshes require an Ethernet interface card or Ethernet router to connect to the 3S200. 3COM servers do not support AppleTalk connections to LaserWriters and can only connect serially.

Kinetics Solution

If you can use a Kinetics FastPath with the EtherLink MC PS/2 product from 3COM (this depends on whether 3COM supports AFP), then the Macintoshes and the LaserWriter can be placed on LocalTalk cabling and be connected to the Ethernet PCs with the FastPath. This configuration does not need the Asynchronous LaserWriter driver for the Macintoshes.

PS/2 Notes

There are six PS/2 models 25, 30, 50, 60, 70, and 80. Each model can also be bought in a different configuration. The low-end models 25 and 30 retain a PC and/or AT bus architecture that works with the Apple LocalTalk PC card.

HyperCard: General Problems with XCMDs

Some XCMDs may cause system crashes or unusual problems to appear. These problems are usually results of poor programming.

This article has been archived and is no longer updated by Apple.

When running a new XCMD, check the result of the command. Try placing this statement into the script after executing the command:

"Put the result into the message"

Here are some possible problems and their solutions when the system locks up:

1) The memory management system is purging needed data, because the XCMD has not taken precautions to protect it.

2) The XCMD has broken the master pointer block, and the problem is not uncovered until some random, future action.

3) The application stack has become fragmented causing an out-of-memory error, because the XCMD has allocated memory, locked it down, and has not removed the data after it was finished.

4) There just is not enough memory available.

There are several ways for XCMDs to crash. Almost all are due to bad programming and trying to use HyperCard in ways for which it was not designed. Anyone using an XCMD needs to test the XCMD in a stack by itself and slowly add and execute other XCMDs. Any one of them may be fragmenting the stack, corrupting the master pointer block, or using up memory by leaving data floating around.

Apple does not support extensions that are not part of the HyperTalk language. The ability to add extensions has been created so that programmers can enhance their stacks. However, each programmer must take the responsibility to check for errors and report any problems to the user when writing the XCMD or XFCN. Programmers who are using extensions from unknown sources must take on the consequences.

Finally, a user's needs may not be appropriate for the capabilities of HyperCard. There are some supported XCMDs, like those available within legitimate HyperCard software products. We suggest HyperTalk programmers use only those XCMDs that they are confident with or that are supported if any future problems develop.

There are many other programming environments that support and handle advanced programming requirements. HyperTalk is not meant to be a replacement for programming languages like Pascal or C.

Mac OS 9: Voice Password Can‘t Find a Microphone

I am trying to use the Voice Verification feature of Multiple Users under OS 9. I was able to successfully set up a voice password, but when I try to use it when logging in, the computer tells me it can't find a microphone.
This article has been archived and is no longer updated by Apple.
Possible Solution:

Try installing Speech Recognition from the OS 9 installer. It is likely that you are inadvertently using an older version of Speech Recognition than the one that comes with OS 9.

Possible solution:

The external mic you used to create the password has been unplugged, and the voice print doesn't match using the computer's built-in mic. Plug the external microphone back in, or change the voice print password using the built-in mic instead.

This error is misleading in this case, since you must authenticate using the same microphone that you used to create your voiceprint. The voice authentication technology takes into account the inherent properties of the microphone while saving the voice print. If you will not normally have the external microphone available at login time, you should create a new voice print using the built-in microphone.

AppleShare IP 6.3: Cannot Connect to Admin Agent After 5 Connections

Attempting to connect to the Mac OS Server Admin Agent and then canceling without entering a user name and password from Mac OS Server Admin leaves the Agent's window showing the connection as a current user. If I connect and cancel a few more times, I can reach the maximum number of five and the subsequent connections are rejected. At this point, I can quit out of Mac OS Server Admin, but not quit out of Mac OS Server Admin Agent.

This article has been archived and is no longer updated by Apple.

Possible Solution:

Wait 60 seconds before trying to connect again.

The software is behaving correctly. The server sees no name and and no password as a bad connection and waits for a timeout. The server waits 1 second, 2 seconds, 4 seconds, and so forth, to 60 seconds before rejecting a connection. It is during this time that the number of connected users can build up to the maximum. The number will drop back down after no more than 60 seconds from the time of the first connection. You will not be allowed to quit the Mac OS Server Admin Agent until the last connection times out.

At Ease 5.0.x: Is Not Qualified With iMac, iBook, Power Mac G4 Models

This article discusses questions regarding using At Ease 5.0.x on the following products:

- iMac (Slot Loading)
- iMac DV (Slot Loading)
- iMac DV Special Edition (Slot Loading)
- iBook
- Power Mac G4 (AGP)
- Macintosh Server G4

This article has been archived and is no longer updated by Apple.

Question:
Can I use At Ease 5.0.x on any of the products listed above?

Answer:
At Ease 5.0.x does not function on these products.

Question:
Since At Ease will not work on these new products, what technology can I use instead of At Ease?

Answer:
In March of 1999, Apple introduced a powerful new product called Macintosh Manager in conjunction with Mac OS X Server, Apple's new server operating system. Macintosh Manager provides a significant increase in functionality over At Ease for Workgroups, and together with Mac OS X Server represents the future of Apple's network management technology. To ease the transition to Macintosh Manager networks, Macintosh Management Server version 1.2 will supports AppleShare IP 6.3. The latest version offers the same functionality and compatibility on both platforms.

Question:
What are some of the advantages of Macintosh Manager?

Answer:
In addition to support for new hardware and operating systems, Macintosh Manager supports a larger number of users and better control over Preferences, Printers, and other resources.

Question:
With what clients can Macintosh Manager be used?

Answer:
Macintosh Manager has been optimized to work with the multi-user environment introduced in Mac OS 9. However, it also includes a client installer that can be freely used with any client running Mac OS 8.1 or later.

Question:
With what server software can Macintosh Manager be used?

Answer:
Macintosh Manager can be used with Mac OS X Server and Macintosh Management Server. Macintosh Management Server 1.2 supports AppleShare IP 6.3 and offers the same functionality and compatibility on both platforms, as well as unlimited client access.

Question:
How can I get the Macintosh Manager server?

Answer:
The original version of the Macintosh Manager server is already available as part of the initial release of Mac OS X Server. The new version is available as part of the Mac OS X Server 1.2 upgrade, and as a free web update to AppleShare IP 6.3.

Question:
Will Apple provide any information on how to migrate from At Ease to Macintosh Manager?

Answer:
To further assist customers with existing At Ease for Workgroup networks, Apple will provide a detailed transition guide that describes the benefits of Macintosh Manager and the steps necessary for a smooth, orderly transition to either an AppleShare IP-based network or a Mac OS X Server-based network.

AppleShare IP 6.3: Not Tested With At Ease Server

I have a server running AppleShare IP 6.2 and At Ease Server 5.0.2. Can I upgrade my server to AppleShare IP 6.3?
This article has been archived and is no longer updated by Apple.
At Ease for Workgroups has not been qualified for use with AppleShare IP 6.3 servers. Customers currently using At Ease are encouraged to migrate to Macintosh Manager in order to provide workstation security and management of user preferences.

Macintosh Manager is supported for servers running AppleShare IP 6.1, 6.2 and 6.3 as well as being included with Mac OS X Server.

The Macintosh Manager client software supports workstations running Mac OS 7.6.1, Mac OS 8.0-8.6 and Mac OS 9.

The following software can be downloaded from the Apple Software Updates Web site at http://www.apple.com/swupdates.

- Macintosh Manager Server 1.2.2 for AppleShare.
- Macintosh Manager Server 1.2 for Mac OS X Server.
- Macintosh Manager 1.3 client software.

Mac OS 9: Location Manager and Multiple Users

I've set up a number of users using the Multiple Users control panel in Mac OS 9. However, I've noticed that when I try to switch network settings as a user other than the Owner using the Location Manager control strip, not all of the settings change the way I would expect.
This article has been archived and is no longer updated by Apple.
Normal, Limited, and Panels users do not have access privileges to change network or File Sharing settings. So, Location scripts that attempt to change these settings will fail if launched in these environments. In turn, Location Manager may stop functioning properly if this is attempted. Location Manager also gives the user access to other settings that the Owner/Administrator may not want changed.

If you need to allow users other than the Owner to change network settings, consider setting Location Manager to ask the user for a location during the startup process. You can find this setting in the Location Manager control panel by choosing Preferences (see figure 1 below) from the Edit menu. Using this method will allow users to change their location _before_ logging in as a specific user, but each user will need to restart the machine to change locations.

In order to prevent users other than the owner from experiencing difficulties when using Location Manager in the Finder or Panels environment, consider one or more of the following:

- Relocate or duplicate the Location Manager control panel to a folder on the hard drive that is only accessible by the users you intend to give access to these controls.
- Disable the Location Manager control strip module by removing it from the Control Strip Modules folder located at the root level of the System Folder.
- And/or, Disable individual Location Manager modules located in the Location Manager Modules folder in the Extensions folder to completely prevent attempts to change specific settings using Location Manager.

AppleShare IP 6.3: Installing Mac OS Server Admin From the Server

On page 13 of "Getting Started with ASIP 6.3" I read:

> **Installing Mac OS Server Admin on an Administration Workstation**
>
> To install Mac OS Server Admin on a workstation, follow these steps:
> 1. Insert the AppleShare IP 6.3 CD into the CD-ROM drive of the workstation.

I downloaded the AppleShare IP 6.3 update from the web, and I don't have an installation CD. How can I install Mac OS Server Admin on a remote computer?

This article has been archived and is no longer updated by Apple.

The Mac OS Server Admin Installer is installed on your server when you update to AppleShare IP 6.3. To install it on a remote client, simply connect to the server hard disk as the Administrator and locate the folder "Mac OS Server Admin Install." Copy this folder to the client's hard drive and follow the installation instructions.

AppleShare IP 6.3 Does Not Require OpenDoc

The AppleShare IP Manager, part of AppleShare IP from version 5 through version 6.2, required that OpenDoc be installed. AppleShare IP 6.3 and the new Mac OS Server Admin no longer require OpenDoc. How do I remove OpenDoc?
This article has been archived and is no longer updated by Apple.
To remove OpenDoc drag the following items on your computer to the Trash then restart the computer.

Figure 1, OpenDoc system software (in the Extensions folder)

Figure 2, The Editors folder (in the System Folder)

Figure 3, The Stationery folder (at the root level of your hard disk)

Mac OS 9: Remote Access Dials Automatically When Opening Network Browser

After installing Mac OS 9, whenever I open the Network Browser my computer dials out to my ISP. Under previous versions of the Mac OS this did not occur. Why does this occur, and how can I stop it?
This article has been archived and is no longer updated by Apple.
Mac OS 9's Network Browser allows for browsing of certain TCP/IP based services (Web, File, FTP). If the TCP/IP Control Panel is configured to connect via "PPP" and the Remote Access Control Panel is configured to "Connect automatically when starting TCP/IP applications" then a connection attempt will be initiated when opening the Network Browser.

Should you not desire this behavior, use the Chooser to browse for AppleTalk services then Network Browser will not initiate any dial-up connections. Alternatively, deselecting the "Connect Automatically when starting TCP/IP applications" option within the Remote Access Control Panel will allow you to browse AppleTalk services within the Network Browser, but will require that you manually initiate a connection to your ISP to browse TCP/IP-based services.

Under previous versions of the Mac OS the Network Browser's functionality was limited to browsing of AppleTalk services only and thus did not produce this behavior.

Mac OS 9: Using Sherlock 2 to Search a Folder‘s Contents

This article discusses how to use Sherlock 2 to search the contents of a particular folder instead of the whole hard disk.
This article has been archived and is no longer updated by Apple.
To limit your search to a particular folder, drag it from the Finder to the Sherlock 2 volume and folder list.

1. Click the Files button in Sherlock 2 (the one with the picture of the hard disk).
2. Click the appropriate search type button (File Names, Contents, Custom...).
3. Drag the folder(s) you want to search from the Finder into the volumes and folder list in the Sherlock 2 window. You should already see your computer's hard disk volumes in this list. The folder's icon will now appear there.
4. Click the On checkbox next to the the folder(s) you want to search.
5. Enter the text or search criteria in the search field.
6. Click the Magnifying Glass button.

To remove a folder from Sherlock 2's volume and folder list, drag the its icon from the list to the Trash.

Mac OS X Server: Configure AppleTalk Via the Assistant

I want to turn on AppleTalk on my Mac OS X Server, so I added AppleTalk as a node via the "Computer Settings"->"Network" menu, and I restarted the Mac OS X Server, but I don't see the server in the Chooser.
This article has been archived and is no longer updated by Apple.
If Mac OS X was not configured to use AppleTalk via the Assistant, then turning on AppleTalk via the "Computer Settings"->"Network" menu won't work.

To make your Mac OS X Server an AppleShare file server via AppleTalk, use the Setup Assistant. In the Setup Assistant, select Apple File Services, then click on the right arrow to go to the "Review Settings" panel and click on the "Go Ahead" button to apply the change.

Mac OS 9: Installing on NuBus-based Power Macintosh Computers

I'm trying to upgrade my system software to Mac OS 9. When the computer is started up from the hard disk I get the following message:

"This Computer requires that you boot from the Mac OS 9 CD to perform the installation."
This article has been archived and is no longer updated by Apple.
Installing Mac OS 9 on all Power Macintosh 6100, 7100, 8100 family computers requires that the computer be started up under Mac OS 9--usually from the CD. The Mac OS 9 installer makes sure that NuBus-based computers such as these are running Mac OS 9 before it will continue with an installation.

You can install Mac OS 9 on these computers by either:

- Starting up from the Mac OS 9 installation disc and then running the installer
- Starting up from an external hard drive that already has Mac OS 9 installed

Installing to an internal drive in one of these computers can be completed by:

- inserting the Mac OS 9 install disc on a locally attached CD-ROM drive
- sharing the Mac OS 9 disc from another computer, then connecting to that volume over a network
- copying the installation files to the same external hard drive the computer used to start up

Mac OS 9: Creating Voice Prints on iMac (Slot Loading) Computers

I'm using Mac OS 9 on iMac (Slot Loading). While trying to record a voice print, I frequently get the error message: "You may have clicked the stop button too soon. Try recording the phrase again."

Sometimes when I finally make it through the four recordings, an error appears saying: "The variations between your recordings may make your voice print less secure."

What is wrong?
This article has been archived and is no longer updated by Apple.
Noise from the iMac's internal disk drive is being heard by the microphone and triggering the "clicked too soon" message.

As much tuning as possible of voice verification has been done. You should just patiently keep trying, and possibly close the door of the room where the iMac is located to decrease other background noise.

Mac OS 9: Multiple Users Does Not Accept Double-Byte Passwords

Using Japanese Mac OS 9, I filled in owner name, owner password, and computer name with Japanese characters using Kotoeri. After enabling Multiple Users, I cannot login.
This article has been archived and is no longer updated by Apple.
Although the File Sharing control panel supports double-byte character input, the Multiple Users Login panel in Mac OS 9 is not double-byte aware. Multiple Users will not recognize passwords created with double-byte input methods.

File Sharing in Japanese Mac OS 9 defaults the owner password to US (Roman characters) but allows the use other input methods (Japanese characters). If you plan on using Multiple Users on a double-byte-aware Mac OS, you should use the default Roman input method for passwords.

If you have created a double-byte password and enabled Multiple Users, to get logged in as the owner, you must start up with Extensions off, by holding the Shift key while restarting, and then throw away the Multi-User Prefs file from the Preferences folder. Enter new data in the File Sharing control panel using a Roman input method, before enabling Multiple Users again.

PowerBook G3 Series (Bronze keyboard): Printer Error After Waking From Sleep

My PowerBook G3 Series (Bronze keyboard) has difficulty printing to a USB printer after it wakes from sleep. It may display a message that it cannot find the printer; it may crash or hang; or it may report that an application unexpectedly quit because of a Type 1, 3, or 11 error. After it wakes from sleep two printers appear in the Chooser at USB Ports 1 and USB Port 2, even though only one USB printer is physically connected to the PowerBook.

This article has been archived and is no longer updated by Apple.

This is a potential issue with the PowerBook G3 Series (Bronze keyboard) running Mac OS 8.6 or 9.0 when a printer is connected using an USB to Parallel adapter cable, sometimes referred to as a dongle. While this issue is being investigated, if you encounter these errors consider:

- - If the printer has true USB support, use a native USB A-to-B cable instead of an adapter cable.
- - Connect the printer cable to the PowerBook only when you intend to print.
- - If the printer cable remains connected during a sleep/wake cycle, restart the computer after it wakes from sleep prior to printing.

HyperCard 2.0: New Product Features (1 of 2)

This article has been archived and is no longer updated by Apple.

OVERVIEW
========

HyperCard 2.0 is the most-significant, major enhancement to HyperCard since the first version, which was introduced to the public in 1987. There are more than 40 new features in HyperCard 2.0. It runs on all Macintosh computers with the 128K or later ROM and 1MB of memory. Displaying multiple stacks and large cards in their entirety, and using the paint tools will require more memory. Here are a few of the main changes:

- Variable card sizes
- Multiple stacks open at same time
- Styled text in fields
- Runs existing HyperCard stacks with one-way conversion to 2.0 format
- Printing improvements
- Extended XCMD interface
- Enhancements to HyperTalk
- Modal script editor
- Debugging
- User-definable menus

PRODUCT FEATURES
================

Variable Card Size

Previously, HyperCard supported only one card size (512 x 342). HyperCard 2.0 allows card windows from 64 x 64 to 1280 x 1280 pixels.

On the right side of the dialog, you can select one of seven possible standard window sizes from the Card size pop-up menu. You can change the card size any time, but all cards in a given stack are one size. If you reduce the size of a card, none of the fields or buttons that fall outside the new boundaries are lost, just hidden from view. The graphics will stay until they are edited by the paint tools or the stack is compacted, then they are clipped to the new size. You can select a number of default settings for the screen size. These include:

- Small: 416 x 240
- Standard 9" 512 x 342
- Mac II 12" 640 x 480
- MacPaint 575 x 719
- Window 512 x 342
- Screen depends on monitor
- Custom 64x64 to 1024x1024

Multiple Stacks Open Simultaneously

Multiple Windows allow a user to have several stacks open at one time. There will be one window for each stack that is open. Users can have as many stacks open as available RAM space will allow. Only one window is allowed per stack and only one card from a given stack may be displays at the same time.

Text Enhancements

- Styled Text in Fields: HyperCard 2.0 lets a text field contain multiple fonts, styles, and sizes. The text can be changed by selecting the text and then choosing "Text Style..." from the Edit menu or selecting an item from the Font or Style menu. You can also find or set the attributes of any range

of characters using HyperTalk.

- Word Wrap: Word wrap has been changed so only a space character will break up a word at the end of a line. In past versions, HyperCard would break any string with punctuation at the end of a line.

- HotText means that any text within a locked text field can be accessed by a number of new HyperTalk commands. This lets a HyperCard developer create stacks that respond to user mouse clicks in a text field. The commands are:

ClickText
ClickChunk
ClickLine

ClickText returns the text characters that were clicked. ClickChunk returns the range of characters. ClickLine returns the line that was clicked (e.g., Line 5 of card field 2).

You can use a "Group" style to override the standard grouping of text. This lets the stack creator join two or more words together and have them act as one word. When text is joined using Group style, the ClickText and ClickChunk change to return the combined words.

Not Grouped Grouped
---------- -------
ClickText FINDER FINDER 5.3
ClickChunk char 1 to 6 of cd field 3 char 1 to 10 of cd field 3

- Shared Background Text: lets designers enter text in a background field and have the text appear on every card of that background. In the past, text had to be "painted" on or entered in every card that used that background.

Printing Enhancements

HyperCard 2.0 has improved printing abilities:

- Design custom reports for a single stack
- Create and save multiple reports for a stack (up to 7)
- Print fields
- Print the entire contents of a scrolling text field
- Print portions of a card
- Print the value of any HyperTalk expression using HyperTalk
- Print text field in same font as they appear on the screen
- Prints to non LaserWriter devices (fax modem)

When you print a report, you must specify the items to print in by using the menu items that come up when you select Print Report. These items are no longer in the Print Reports dialog box.

Mac OS 8.1: Computer Stops Responding When Calculating Folder Size on Server

This article explains why a Macintosh computer may appear to stop responding when the Calculate Folder Sizes option is selected.
This article has been archived and is no longer updated by Apple.

Symptom

On a Macintosh computer running Mac OS 8.1 and AppleShare 6, the computer appears to stop responding when you open a folder on a server volume. This occurs if the window is set to View as List and the option to Calculate Folder Sizes is selected.

Solution

This will happen if you do not have read access to all of the folders in this window. Your computer will appear to stop responding with the network arrows visible in the upper left corner of the screen while the Finder attempts to calculate the size of the folder to which you do not have access.

You will be able to continue working on your computer, but performance will be slow until you deselect the option to Calculate Folder Sizes. Your computer will also stop responding if you attempt to Get Info on a folder to which you do not have read access.

This issue is has been resolved in Mac OS 8.5 and later.

QuickTime 4.1: About AppleScript and QuickTime Player

This article describes the AppleScript support in QuickTime Player 4.1.
This article has been archived and is no longer updated by Apple.

About AppleScript and QuickTime Player

With QuickTime 4.1, you can use AppleScript to automate QuickTime Player.

For example, you can:

- open a movie and tell it to play for a specific duration
- automate the conversion of movies from one format to another using export
- automate hinting of movies for streaming
- play a movie from a URL
- script playback of movies with control over size, rate, volume, balance, and looping
- automate annotation of movies
- inventory movie contents (number of tracks, files used, annotations)
- adjust track playback properties such as start time, volume, and layer

QuickTime Player 4.1 is not a recordable application.

Final Cut Pro 1.2.5: Does Not Include FireWire Cable

Final Cut Pro 1.2.5 does not include a FireWire cable.
This article has been archived and is no longer updated by Apple.
Although Final Cut Pro 1.0 included a FireWire cable, Final Cut Pro 1.2.5 does not include a cable because some Power Macintosh G4 and iMac DV computers already ship with a FireWire cable.

The side of the Final Cut Pro 1.2 box specifically lists what the package includes and the FireWire cable is not listed. Unfortunately, the Final Cut Pro User's Guide mentions an included FireWire cable. This will be fixed in future versions of the documentation.

You may have bought a Macintosh model that does not include a FireWire cable and don't know where to get one. FireWire cables can be purchased at computer resellers, video equipment stores, and electronics stores. The cable can also be purchased through the Apple Store.
Published Date: Feb 18, 2012

QuickTime 4.1: Issue With QTVR Hotspots

There is a potential issue with QuickTime 4.1 where URL hotspots embedded in QuickTime VR movies no longer work.
This article has been archived and is no longer updated by Apple.
Note: This issue is addressed with QuickTime 4.1.1. Find more information on QuickTime 4.1.1 at **http://www.apple.com/quicktime/.**

URL links that rely on the "Hotspot" parameter of an embed tag do not work with QuickTime 4.1. URL links originally authored as URL hotspots work correctly.

Here are some workarounds that may be helpful to developers

1. If your movie does not include hotspots with neighboring ids (which is the case with most movies made with QTVRAS) you can double-up your hotspot parameters in the embed tag:

    Hotspot10="http://www.apple.com"

would become:

    Hotspot10="http://www.apple.com"
    Hotspot11="http://www.apple.com"

This will work with QuickTime 4.1.1, 4.1, and older versions.

2. If this does not work for your content, you may need to modify or re-author your movies. If you have the source files in the authoring tool's format you can modify and re-make the files.

Also, VRTools' application "ConVRter" allows you to change a hotspot's type to "URL" and/or edit its URL string. ConVRter is available from http://www.vrtools.com.

Final Cut Pro 1.2: Using With Mac OS 9 Multiple Users Feature

This article discusses some potential issues with Final Cut Pro 1.2.1 when using the Multiple Users feature of Mac OS 9.
This article has been archived and is no longer updated by Apple.
When the Multiple Users feature of Mac OS 9 is turned on, limited users are unable to change Final Cut Pro preferences. In addition, Final Cut Pro will quit with a Type 2 error when a limited user chooses the Preferences command from the Edit menu.

As a workaround, you can copy the entire Final Cut Pro folder to the limited user's Documents folder (an alias to this folder is on the desktop). Also, make sure the limited user only has access to the Final Cut Pro application in this folder.

Macintosh SCSI Termination: A Brief Explanation

Is the Macintosh SCSI connector terminated on the logic board? In other words, are both ends of the chain terminated or only the last peripheral?

This article has been archived and is no longer updated by Apple.

The Macintosh systems that have SCSI ports are not terminated on the logic board. One system, the Macintosh IIfx, when shipped without an internal hard drive, comes with a terminator plugged into the internal SCSI connector. If an internal hard drive is installed in a Macintosh system, it should be terminated. The internal hard drive is the first device in a SCSI chain. The last device in the SCSI chain should also be terminated.

Typically, a Macintosh system with only one SCSI device needs only one terminator. The exception to this is the Macintosh IIfx when it has a single SCSI device attached on the external SCSI connector. In this case, there should be the internal terminator that came with Macintosh IIfx and a terminator on the external SCSI device.

Macintosh Pascal Discontinued but Supported: Update

Is there a product called MacPascal? If yes, what is the latest version, and is it an Apple's product?

This article has been archived and is no longer updated by Apple.
Macintosh Pascal was discontinued many years ago. The latest version shipped by Apple was version 2.1. Although we no longer ship it, we continue to support the product (though we rarely get any questions on it since most people have migrated to newer products).

There are many substitutes, including Think Pascal from Symantec, which could be used in conjunction with an interactive tutorial called Just Enough Pascal, also from Symantec (these, as well as others, are described in the buyer's guides on AppleLink).

We'll update the article "Macintosh Pascal Is Discontinued But Supported" in the Tech Info Library with this information.

Mac OS X Server 1.x: About NetBoot Server Software

About NetBoot Server Software

This document contains late-breaking information that supplements the information in your installation manual.
This article has been archived and is no longer updated by Apple.
Note: This article pertains to Mac OS X Server versions 1.x, which were released prior to May 2001.

Updating the firmware on NetBoot client computers

Before using an iMac as a NetBoot client computer, you should update its firmware to the latest version of the software using the iMac Firmware Updater included on the NetBoot installation CD. Updating the firmware is especially important if you use the NetBoot server for virtual memory storage. The iMac Firmware Updater fixes a known problem with using virtual memory over the network to the NetBoot server.

You can use the Power Macintosh G3 model released in 1999 (Blue and White) as a NetBoot client, but it also requires updating the firmware if the NetBoot server is used for virtual memory storage. A firmware updater will be available soon on the Apple Support Web site at http://www.apple.com/support. Until the firmware updater is available, you can use a Power Macintosh G3 1999 model as a NetBoot client if you set it to use its internal hard disk for virtual memory.

NetBoot server information

AppleTalk seed routers are required on all NetBoot server ports

If you use more than one port on your NetBoot server, you need to be sure AppleTalk is in routing mode. There must be a seed router for every port that's connected to a subnet. The seed router can be the NetBoot server or an AppleTalk router.

If the NetBoot server is the seed router for a subnet, you need to enter valid AppleTalk network numbers when you use the NetBoot Server Setup Assistant. It's important that you enter the correct numbers, as the NetBoot Server Setup Assistant can not check to see if the numbers are valid. If you enter the wrong values, AppleTalk won't start up.

If AppleTalk doesn't start up, which you can check by using the ProcessViewer, you can set up the NetBoot server so that only one port is used. Once you obtain the correct network numbers, you can set up other ports.

Turning off the Macintosh Manager client software

If you don't want to use Macintosh Manager client software, open the Extensions Manager control panel and turn off the Macintosh Manager extensions. You must do this at the same time you are making your changes to NetBoot HD image, otherwise the extension won't be disabled. If you disable Macintosh Manager client software, computers start up from the NetBoot server, but a login window doesn't appear and none of the Macintosh Manager options you set take effect.

Resetting PRAM disables starting up from a NetBoot server

Your computer stores information in an area of memory called parameter RAM (PRAM). Resetting the PRAM replaces the information stored there with the default (original) settings. If you reset PRAM, the computer will not start up from the NetBoot server. If PRAM is reset and your computer was previously a NetBoot client, hold down the N key while pressing the Power key to restart your computer from the NetBoot server.

Changing volume names

You can change the name of NetBoot server volumes by using HDNamer. However, if you do you must reinstall the NetBoot server software.

Moving the Macintosh Manager folder

The first time you use Macintosh Manager, it sets up a folder on the Apple file services volume of your Mac OS X Server. This folder, called Macintosh Manager, is set up as a share point and is used to store information about users, preferences, and options.

If the Apple file services volume on which the Macintosh Manager folder is located becomes full, you can move the folder to another volume on your Mac OS X Server computer.

To move the Macintosh Manager folder:

1. Make sure no client computers are logged in to Macintosh Manager.
2. Log in to Mac OS X Server and use the ProcessViewer to turn off Macintosh Manager.
3. On a local-startup computer, use the Chooser to mount the Apple file services volume that currently contains the Macintosh Manager

folder and the volume where you want to move the folder. You must log in to each volume as administrator (or root).
4. Copy the Macintosh Manager folder from the root level of the current volume to the root level of the new volume.
5. Use a Web browser to log in to Remote Administration for Apple file services. Be sure to log in as an administrator.
6. In Disks & Share Points, locate the new Macintosh Manager folder and make it a share point. For more information about setting up a share point, see the onscreen help.
7. Change the owner of the new Macintosh Manager folder to Macintosh Manager User.
8. Select "Make all enclosed folders like this one," then click Save.
9. In Disks & Share Points, locate the folder that used to be the Macintosh Manager folder and remove the share point.
10. Delete the old Macintosh Manager folder.
11. Restart the server.

Quitting applications before using NetBoot Desktop Admin

Before you use NetBoot Desktop Admin, quit any applications you have open. If you have other applications open when you open NetBoot Desktop Admin, a message tells you to quit the other applications. If you click Continue, NetBoot Desktop Admin attempts to close all the applications. However, some applications may not close, so NetBoot Desktop Admin will wait indefinitely.

NetBoot client computer Iinformation

Changing the default home page in your Netscape browser

The default home page in the Internet control panel is http://livepage.apple.com. If you change the default home page in your Netscape browser, the setting is not saved when you log out of the computer. The next time you log in and open the browser, you'll see http://livepage.apple.com. To reset the default home page for all users, change the default in the application in the NetBoot HD image.

Applications you install on the Applications HD image may not work properly

The Applications HD image is mounted by a NetBoot client computer as a read-only volume. The NetBoot HD, which contains the Mac OS system the NetBoot client computers use, is a read-write volume. Applications that store information in files kept in the Preferences folder should work correctly because changes can be saved. Those that save information in files in their own application folder may not work properly. As an alternative, you can install the application on the NetBoot HD image. This will work only if the information the application saves in a file does not need to be preserved when the client computer is restarted.

Memory control panel

The information in the Memory control panel for a NetBoot client computer may be incorrect. To view the actual memory settings, choose About This Computer from the Apple menu.

Mac OS X Server: About Release 1.2

About Mac OS X Server Release 1.2
This document contains important information about Mac OS X Server, Release 1.2, including Apple file services, NetBoot, Macintosh Manager 1.1, and WebObjects.
This article has been archived and is no longer updated by Apple.
Information about Mac OS X Server

Late-breaking news about Mac OS X Server

- This release of Mac OS X Server includes the Apache version 1.3.9 software, a later version than stated in the About Mac OS X Server Release 1.2 printed booklet.
- The Mac OS application (MacOS.app), which provides the Mac OS Compatibility Environment, now has Mac OS 8.6 installed. Do not upgrade to a later version of the Mac OS.
- This release includes the NetProbe.app application. It's located in the Demos folder in the System folder on your computer.
- The installer.sh command line utility program has been removed from this release.

Information about hardware supported by Mac OS X Server

- This release of Mac OS X Server includes support for Power Mac G4 and Macintosh Server G4 computers. Keep these points in mind about new features provided by these computers:
- Some Power Mac G4 and Macintosh Server G4 computers have a redundant power supply. Mac OS X Server can detect if the redundant power supply unit has degraded and sends a message to the Console if it does.
- The Power Mac G4 and Macintosh Server G4 has two USB ports. Mac OS X Server can detect devices on only one USB port at a time. Therefore, you must connect your mouse to your keyboard.

Information about expansion cards supported by Mac OS X Server
This release of Mac OS X Server supports the following expansion cards.

For the original (platinum) Macintosh Server G3:

- Single-port 10/100 Ethernet card: Zynx
- Single-channel U1 SCSI card: ATTO PSC

Note: If you install Mac OS X Server on an original (platinum) Power Macintosh G3 computer with an ATTO single-channel Express PCI-PCS card for the first time, you need to use the Mac OS SCSI Card Updater 1.1 program to update the ATTO firmware before you install the server software. The Updater program is located in the Utilities folder on the Mac OS X Server CD.

For the Macintosh Server G3 (blue and white):

- Single-channel U2 SCSI card: Adaptec 2940
- Dual-channel U2 SCSI card: Adaptec 3950
- Ultra SCSI card (Legacy): Adaptec 2930
- Gigabit card: Sun
- 4-Port 10/100 Ethernet card: D-Link

For the Macintosh Server G4:

- Dual-channel U2 SCSI card: ATTO UL2D
- Ultra SCSI card (Legacy): Adaptec 2930
- 4-Port 10/100 Ethernet card: D-Link

Information about installing WebObjects software
The WebObjects disc installs earlier versions of the WebObjects adaptors than the adaptors available on the Mac OS X Server CD. If you install the WebObjects software, you will need to install the newer WebObjects adaptors using the Installer on the Mac OS X Server CD. To do so, follow these steps:

1. After you install the WebObjects software, restart your computer and log in as Administrator.
2. Insert the Mac OS X Server CD.
3. Open the Packages folder (in the `/System/Installation` folder) and double-click the WOAdaptor.pkg file.
4. Follow the onscreen instructions to install the software.

5. Install the WebObjects adaptors in the default location shown in the Installer.

Problems resolved and other improvements

- This release fixes a number of problems that improve the stability and reliability of Mac OS X Server. The Setup Assistant, kernel, NetInfo, networking, and the core foundation have also been improved.
- This release fixes a number of reliability problems with the Mac OS Standard and Mac OS Extended format file system that could result in your server crashing.
- A problem in the TCP/IP software that resulted in the computer hanging or crashing when the network was very busy has been fixed.
- A problem that prevented using volumes larger than 200 gigabytes (GB) has been fixed.
- After you print to an LPD printer, you need to restart the LPD printer daemon by logging in as Administrator and typing the following:

```
/user/libexec/lpd&
```

Known issue with OmniBackup Personal Edition

If the resolution of your monitor is set to 640 x 480, you will not be able to see parts of some windows and dialog boxes in OmniBackup Personal Edition. To solve this problem, set the resolution of your monitor to at least 800 x 600.

About Apple file services

This section contains important information about Apple file services and Remote Server Administration.

Remote Server Administration browser compatibility issues

- Before logging in to Remote Server Administration from your browser, open Preferences and set the Advanced cache settings to Every time (for Netscape Navigator) or Always (for Internet Explorer).

- To use Microsoft Internet Explorer to access Remote Server Administration from a Macintosh computer, you need to select Mac OS Runtime for Java as the Java virtual machine. To do so, open the Edit menu in Internet Explorer and choose Preferences, then open the Web Browser category and select Java. Open the "Java virtual machine" pop-up menu and choose Apple MRJ.

  You should also make sure your computer has Mac OS Runtime for Java version 2.0 or later installed. To do so, check the version of the MRJLib file, which is in the MRJ Libraries folder (in the Extensions folder in the System Folder).

  To log in to Remote Server Administration using an administrator user name that contains two-byte characters, such as Japanese, you must have Mac OS Runtime for Java version 2.1.1 or later installed.
- To access Remote Server Administration from a Web browser on a computer with a European or Japanese system installed, make sure you have selected the correct language and default character set encoding in the Web browser. On Mac OS computers, you must also have Mac OS Runtime for Java version 2.1.1 or later installed to log in with an administrator user name that contains special characters.

  If you are using Netscape Navigator or Communicator, open the Edit menu and choose Preferences, then open the Navigator category and select Languages. If necessary, click Add to add French, German, or Japanese to the list. Remove other languages from the list. Finally, open the View menu, choose Character Set, then choose Western (ISO-8559-1) as the character set for European languages or Japanese (Shift_JIS) for Japanese.

  If you are using Microsoft Internet Explorer, open the Edit menu and choose Preferences, then open the Web Browser category and select Language/Fonts. Open the Language pop-up menu and choose French, German, or Japanese. Then open the "Character set" pop-up menu and choose Western (Latin1) for European languages or Japanese (Shift-JIS) for Japanese.
- If you connect to your server through a proxy using Netscape Communicator, you may experience timeout problems and data may not be updated on the server. If you experience this problem, use a direct connection to the server. If you must use a proxy, talk to your proxy server administrator about enabling HTTP write access to the Mac OS X Server.

- If you are using Microsoft Internet Explorer with Remote Administration, you should set the preferred memory size to at least 12 MB.

Issues with using Remote Server Administration

- To log in to Remote Server Administration, your user account must exist in the NetInfo database on the same server as the Apple file services. All accounts created using Setup Assistant, NetworkManager, and Remote Server Administration are stored in the local NetInfo database.
- You can only use 7-bit characters for administrator and user passwords. These are the standard ASCII characters which include control characters, alphabetic and numeric characters, and standard keyboard characters.
- Due to a limitation in Netscape Java, the Caps Lock key is not recognized to enter uppercase letters in a password. To use uppercase letters in a password, press the Shift key.

- If you are using Netscape Navigator or Netscape Communicator with Remote Administration, do not click Reload. If you do, you will need to log in to Remote Administration again. You may also need to log in again if you resize the browser's window.
- Do not use the browser's Back button to return to a page in Remote Server Administration. If you do, settings you have made in the page may appear to be different.
- The server access log (AppleFileAccess) is not turned on automatically. To turn on access logging in Remote Administration, click File, then click Server Settings, select the Log Server Access checkbox, and click Save.
- For Internet aliases and group names, you can use only lowercase letters, numbers, and the underscore character.
- The Server Administration Help on your Mac OS X Server states that to troubleshoot problems logging into Remote Administration you should open the Process Viewer to confirm that the AdminWebServer and RemoteAdminServer processes are running. Instead of "AdminWebServer," you should see "apache."
- When you create or edit a user account, the user name and Internet alias can be the same.
- The Remote Admin documentation states that the maximum number of groups you can assign to a user account is 42. There is no longer a limit on the number of groups you can assign to a user account.
- In the Users section, you will see the Administrator (root), Unprivileged user (nobody), and macos group. Do not change the names of these items.

Issues with Apple file services

- Do not give your server the same name as any other AppleShare File Sharing or Apple file services server on the same zone of the network. Remote Administration does not warn you if you do. However, users trying to log in to the servers may be unable to log in to the server they want to use. Check the server error log (AppleFileError) for information about this problem.
- You cannot change access privileges for read-only volumes, such as CD-ROM discs. You can share folders on these volumes, but files are read-only for everyone.
- If you define more than a few hundred sharepoints on the server, some sharepoint names will not appear in the client's Chooser.
- Folders created by guest users are owned by "Unprivileged user" (nobody). To reassign privileges for these folders, log in to the server computer Administrator (root).
- If you use Setup Assistant to choose a connection to a NetInfo parent server and then turn off the connection using the Network settings panel, for example, and you have configured DNS manually without specifying any DNS server addresses and TCP/IP to get the host name and default router automatically using Bootp, local host information for your server computer may not be saved in the local NetInfo domain. If NetInfo domain does not contain the local host name, Apple file services will not start and any applications that use the local host name will fail. If this happens, open Setup Assistant and make sure you do not have your network services configured this way.
- If Apple file services does not start when you start up your server computer or when you turn on the service using Remote Administration, check the server error log (AppleFileError) for information about startup errors.
- If your network does not have a router, you need to enter the server's IP address in the Router Address field in the TCP/IP control panel on each AppleShare client computer.

Issues with AppleTalk configuration
If AppleTalk isn't configured correctly, it will fail when you start your Mac OS X Server but you will not receive a message about the problem. If this occurs, AppleShare clients will not be able to locate the server in the Chooser and Macintosh Manager clients will not be able to log in to the server.

Note: Because Apple file services can use TCP, Remote Administration will show that the server is running and NetBoot client computers will be able to start up.

If you experience these problems, be sure AppleTalk is configured correctly using the Setup Assistant and Network Settings control panel.
If you configure more than one port on your server computer to use AppleTalk, each port must be connected to a network with an AppleTalk router. If your server computer is acting as the router, make sure it is configured correctly and does not conflict with other AppleTalk routers on the network.

Issues with the AppleShare Client software

- You should always install the latest version of the AppleShare Client software on the computers in your network. The latest version of the AppleShare Client software is version 3.8.6. To get the latest version of the AppleShare Client software, see www.apple.com/support.

  There are two problems you should be aware of if your client computers have earlier versions of AppleShare Client software installed: If your client computers have Mac OS 8.5 or later installed and AppleShare Client version 3.8.1 installed, files that users copy to server volumes may be corrupted in some cases.

  When a user logs in to Apple file services from a computer with AppleShare Client version 3.8.2 installed, the user's password is sent over the network in clear text form. Someone monitoring your network traffic could get a password, such as the Administrator password, thus compromising your network's security.

  To prevent both of these problems, install the latest version of the AppleShare Client on all client computers.
- If you want to change the access privileges of an Apple file services volume from a client computer, only enter a user name in the Owner

box and a group name in the User/Group box in the Sharing window.

About NetBoot server

The NetBoot server now needs only one disk image. The earlier version of NetBoot server included a System disk image and an Application disk image. NetBoot server now only requires the System disk image. You can install applications in the System disk image or you can continue to use the Application disk image. You can also continue to use NetBoot Desktop Admin to change the size and add items to the Application disk image. The NetBoot disk image has Mac OS 9 installed. Mac OS 9 supports netbooting these computers: Power Macintosh G3 (with Open Firmware update), Power Mac G4, iMac, iMac DV, iBook, and PowerBook G3.

IMPORTANT You may operate any NetBoot-compatible version of the Mac OS software on a NetBoot-capable computer, as long as that computer is licensed to operate that particular version of the Mac OS. This means the version of the Mac OS that was included with your Macintosh or any other version for which you've purchased a license. Mac OS X Server and the NetBoot Server license agreement DO NOT include any Mac OS licenses.

A NetBoot client computer using Mac OS 9 requires 64MB of memory. If a NetBoot client computer does not have this much memory, increase Virtual Memory to equal or exceed this amount. (To increase Virtual Memory, use the Memory control panel.)

With this release, you can netboot client computers over Ethernet switches. Users may notice a slight decrease in speed when they start up the netboot clients.

For more information about the NetBoot server, see the About NetBoot Server Read Me. The Read Me is located on the Mac OS partition of your Mac OS X Server.

About Macintosh Manager 1.2

This release of Mac OS X Server includes Macintosh Manager version 1.2. This version of Macintosh Manager lets you manage client computers installed with Mac OS 8.1 through Mac OS 9, including NetBoot client computers using this release of the software. You must use this version of Macintosh Manager to manage client computers with Mac OS 9 installed. The Macintosh Manager 1.2 client software only works with this version of the server.

WARNING If you upgrade the Macintosh Manager server to the new version, you will not be able to revert the server to an older version.

For more information about this version, see the Macintosh Manager Read Me included with this release.

Mac OS X Server 1.2: About Mac OS Compatibility (MacOS.app) v2.2

Mac OS X Server Customer Release Notes: Mac OS Compatibility (MacOS.app) v2.2

Release Notes as of 9 November 1999.

This document describes the Mac OS Compatibility environment shipped with Mac OS X Server 1.2. This environment is implemented by the MacOS.app application, sometimes referred to as the "Blue Box".

This article has been archived and is no longer updated by Apple.

Note: This article pertains to Mac OS X Server version 1.2, which was released prior to May 2001.

Overview

MacOS.app, sometimes referred to as the "Blue Box", is a high-performance, high compatibility environment for running Mac OS software within the Mac OS X Server operating system.

High compatibility is achieved by running Mac OS essentially unchanged in a virtual environment, which appears to be a new Macintosh hardware model. Because of this, the vast majority of Mac OS applications, utilities, extensions and software drivers just work. Software that directly accesses hardware, uses undocumented internal APIs of the Mac OS, or relies on Mac OS managers not yet supported by this release of MacOS.app is not expected to work.

The Mac OS managers not currently supported by this release are those generally associated with hardware not yet fully supported by Mac OS X Server. Such missing functionality is explicitly listed in this document and will likely be provided in subsequent releases of MacOS.app.

This release of MacOS.app comes with Mac OS 8.6 and will only support that version and versions beginning with Mac OS 8.5. Versions of Mac OS prior to Mac OS 8.5 and later than Mac OS 8.6 are not supported and MacOS.app will not allow them to run.

MacOS.app allows you to use your current Mac OS applications to "live" on Mac OS X Server, to explore its new capabilities while preserving your current Mac OS environment.

You are encouraged to read these release notes before running MacOS.app. If you just can't resist, at least read the following "Quick Start" section.

Quick Start

To start MacOS.app, choose MacOS in the Mac OS X Server Apple menu or double-click on "/System/Applications/MacOS.app" in the Workspace File Manager. You may also want to drag an alias onto the Workspace for quicker access to MacOS.app. It is best not to launch MacOS.app from a Terminal window, since it will not result in a clean MacOS.app shutdown when logging out from the Mac OS X Server's Workspace.

The first time you launch MacOS.app, a private Mac OS 8.6 startup disk image (called StartupDisk.img) will be created. The image will be copied and uncompressed into /Local/Library/MacOS/Users/<user name>. This process will take a little time and is accompanied by a dialog box with a progress bar. At the end of creating the startup disk

image, a virtual PRAM file called "PRAM" will also be created in the same directory.

Choosing Shut Down from the Mac OS Finder's Special menu will quit MacOS.app. Similarly, choosing Restart will quit and re-launch MacOS.app. You may also use the Power key, which will bring up the standard Mac OS "Shut Down / Restart" dialog box.

To switch between the Mac OS and Mac OS X Server environments, use the Application menu at the far right of the menu bar. In both MacOS.app and Mac OS X Server, this menu has been extended to list all applications running in both environments, grouped by environment. If you choose an application that is running in the other environment, you will be switched to that environment and the selected application will be activated.

There is a special item in the application menu of each environment that will switch you to the other environment and bring you back to the last application you were using in that environment. That item is called "Mac OS X Server" in the Mac OS environment and "MacOS" in the Mac OS X Server environment.

The following special keys combinations are available when you are in the Mac OS environment, and supersede any Mac OS use of these key combinations:

Command-Return is a shortcut for choosing "Mac OS X Server" from the application menu. Since this may interfere with some applications that use this combination of keys, you may disable it, as discussed under "User Input" in the "Bugs and Compatibility Issues" section.

Command-Shift-Q will force-quit MacOS.app. This would be equivalent to pulling the power plug out of the wall on native Mac OS and should only be used when Mac OS is hung.

All other Mac OS special keys (e.g., Command-Power for NMI - to enter MacsBug) function as expected.

Before installing software, read the section "Use of Disk Image Files", under "Working with Disk Image Files".

System Requirements

The minimum recommended RAM for running Mac OS X Server with MacOS.app is 64 MB.

Each user running MacOS.app on this machine will require a minimum of 225 MB of disk space for the Mac OS 8.6 startup disk image.

Installation

MacOS.app is installed as part of the standard Mac OS X Server installation. Earlier versions of MacOS.app are not compatible with Mac OS X Server.

The installation consists of the following installed items:

`/System/Documentation/ReadMe/MacOS.html`

This release note document.

`/System/Applications/MacOS.app`

The application directory contains the executable file (MacOS), supporting resources and compressed localized Mac OS disk images. The particular localized disk images installed (of English, French, German and Japanese) will depend on your language selection(s) when you install Mac OS X.

`/usr/bin/createimage`

A command-line utility to create new disk image files (discussed under "Working with Disk Image Files").

Features

System Software

MacOS.app currently supports Mac OS 8.6. The supplied StartupDisk.img files contain complete default installations of English language Mac OS 8.6 except for Apple Remote Access and Text-to-Speech. These were omitted to save space and because they rely on features not yet supported by MacOS.app.

Do not attempt to boot MacOS.app from System Folders with versions of Mac OS prior to Mac OS 8.5. You may install Mac OS 8.5 or 8.5.1 using the normal Mac OS installation techniques in MacOS.app.

Virtual Memory

MacOS.app uses a new method for virtual memory, taking advantage of Mac OS X Server's VM system. This method, called "Sparse Virtual Memory", allows application heaps to be protected from each other with "guard" pages of unmapped memory. In addition, it allows a large number of applications to be launched, using disk space for memory as it is needed. The total virtual application memory available is 1024 MB.

MacOS.app always runs on top of Mac OS X Server's Virtual Memory, but Mac OS VM will appear to be off to applications.

Temporary Memory

In native Mac OS, an application's memory heap comes out of the same memory area as temporary memory. Since some applications allocate large fractions of available temporary memory, MacOS.app does not offer the entire unused portion of its 1024 MB sparse virtual address space as temporary memory. Instead, the temporary memory heap is created at startup time, with the size determined by the machine's available physical memory, with a minimum size of about 16 MB. Some applications may require a larger amount of temporary memory in order to run properly, and you can allocate additional temporary memory by setting SysZoneMemorySize to the desired size. For example "defaults write MacOS SysZoneMemorySize 0x10000000" will set the temporary memory size to approximately 256 MB. You may notice this difference in the Finder's "About This Computer" dialog box. In native Mac OS, the first bar (labeled "Mac OS") shows the amount of memory allocated to Mac OS and is usually almost fully in use. In MacOS.app, this bar includes the memory allocated to Mac OS plus the temporary memory allocation. On machines with a large amount of physical memory, this bar will be significantly larger.

File Systems

Throughout this document, "HFS(+)" is used as an abbreviation for "HFS or HFS+". HFS is also known as "Mac OS Standard Format" and HFS+ as "Mac OS Extended Format".

MacOS.app supports file systems on nearly all kinds of disk devices that are supported under the native Mac OS. These include, but are not limited to floppies, CD-ROMs, hard drives, and disk image files stored in the Mac OS X Server file system (UFS). Both SCSI and ATA/IDE (including ATAPI) drives are supported.

Disks can be accessed in one of three modes: Shared, Exclusive, or SCSI. Not all disk modes are available for all disks. The default access mode is Shared mode, except for disk images (which are always accessed in Exclusive mode). In order of highest-to-lowest interoperability with Mac OS X Server applications, the modes are Shared, Exclusive, and SCSI. Conversely, the modes in order of highest-to-lowest compatibility with Mac OS applications are: SCSI, Exclusive, and Shared.

Thus, there is a fundamental tradeoff involved with choosing which mode to use to access a disk. Shared mode was chosen as the default access mode because it provides a high enough level of compatibility to support typical productivity applications, while at the same time permitting access to the same disk via Mac OS X Server applications.

For more information, see the sections entitled "Disk Access Modes" and "Disk Drive Support".

Copy and Paste Between Mac OS and Mac OS X Server

MacOS.app currently supports basic Copy and Paste between Mac OS and Mac OS X Server applications.

Text can be copied (without style information) back and forth between the two kinds of applications. This includes some support for two-byte characters. See the "Bugs and Compatibility Issues" section for more details.

Pictures ('PICT') can be copied from Mac OS to Mac OS X Server applications, but are converted to RTF, which cannot be copied back to Mac OS. Many more data types are expected to be supported in future releases of MacOS.app.

Networking

MacOS.app supports Open Transport AppleTalk and TCP/IP networking using built-in Ethernet and any PCI Ethernet devices supported by Mac OS X Server. LocalTalk (AppleTalk over serial ports) is not supported. As with native Mac OS, AppleTalk networking is active by default if connected to a network.

AppleShare Client as well as Personal File Sharing, AppleShare Server and AppleShare IP Server are fully supported by MacOS.app. Personal Web Sharing is also supported.

Since Mac OS uses a different networking model than Mac OS X Server (Open Transport vs. Sockets), you must use a separate IP address for MacOS.app TCP/IP from that used by Mac OS X Server. This is best accomplished by using a static IP address in the TCP/IP control panel (or by using MacIP - IP over AppleTalk). In previous versions of MacOS.app, when the same IP address was used for Mac OS X Server and MacOS.app, Open Transport reported an error message indicating the reason TCP/IP networking is not available. If the same IP address is used in the present versions of Mac OS X Server and MacOS.app, Open Transport TCP/IP will silently be disabled.

PCI Native Driver Model

MacOS.app partially supports the PCI native driver model. This means that the name registry, DriverServicesLib, and associated libraries are present. However, the Mac OS device tree is currently empty, so no 'ndrv' drivers are loaded.

Video

Unlike Mac OS X Server, MacOS.app can change color depth on the fly and supports multiple monitors in color depths of 8, 16, and 24-bit (256, "thousands" or "millions" of Colors or Grays). However, if Mac OS X Server is in grayscale mode, then MacOS.app will not allow depth changes.

Because of limitations in Mac OS X Server, MacOS.app cannot change resolution (size and scan rate). The resolution must be changed in Mac OS X Server's Preferences application and the changes take effect after logging out of Mac OS X Server.

MacOS.app supports multiple monitors. However, you may set it up to use only one monitor on a multiple-monitor system. MacOS.app assigns the number 0 to the main monitor (the one with the menu bar). Additional monitors are assigned the numbers 1, 2, etc. Setting the Mac OS X Server user preference "MonitorSelect" for MacOS.app to a value that indicates that monitor's assigned number will cause MacOS.app to only use that monitor for displaying video.

For example, from a Mac OS X Server Terminal window:

```
"defaults write MacOS MonitorSelect 0"
```

means only use the main monitor and

```
"defaults write MacOS MonitorSelect 1"
```

means only use the second monitor.

AppleEvents and AppleScript

AppleEvents and AppleScript are supported as usual within MacOS.app and from MacOS.app to scriptable Mac OS X Server applications.

For Mac OS X Server applications to be scriptable, they must use the Scripting Framework. Developer documentation on the use of this framework can be found in /System/Documentation/Developer/YellowBox/ReleaseNotes/

The Script Editor in MacOS.app can target applications that are running in the Mac OS X Server environment. On the local machine, targeting these applications is done the same way that targeting Mac OS applications is done.

For example, if you have a Mac OS X Server application named Sketch, you would target the application with standard AppleScript syntax:

```
tell application "Sketch"
```

```
...
end tell
```

If you are targeting Mac OS X Server applications on other machines, the syntax is slightly different and uses a semicolon between the application name and the host name:

```
tell application "Sketch;hostname"
...
end tell
```

The normal Mac OS syntax to target remote Mac OS X Server applications:

```
tell application "Finder" of machine "machine name" of zone "zone name"
...
end tell
```

is not supported in this release.

The MacOS.app Script Editor cannot get the dictionary information for a Mac OS X Server application in Mac OS X Server 2.0. This functionality will be added in a later release.

By default, Scripting between two machines is turned off for security purposes (similar to Mac OS Program Linking which is turned off as the default). The following information will help you turn on remote AppleEvents and remote AppleScripting.

The remote scripting default is called NSAllowRemoteAppleEvents.

It can be set from a Terminal window like this:

```
defaults write NSGlobalDomain NSAllowRemoteAppleEvents YES
```

It could also be turned on only for certain applications as follows:

```
defaults write Sketch NSAllowRemoteAppleEvents YES
defaults write TextEdit NSAllowRemoteAppleEvents YES
```

An API for using AppleEvents outside of AppleScript in Mac OS X Server applications has not been provided in this release.

Sound Output

Sound output is fully supported by MacOS.app, although breakup may occur during times of heavy CPU usage or memory paging. Occasionally, this may result in sound going silent altogether until the application using sound quits or MacOS.app is restarted. Playing sound in Mac OS X Server and MacOS.app simultaneously will have unpredictable results.

SCSI Manager

The Mac OS SCSI manager is partially supported in this release. It can be used via SCSI Mode for disks, as discussed in the section "Disk Access Modes", and to access non-disk devices (such as scanners and tape drives) which are not in use by Mac OS X Server.

Both the original SCSI Manager and SCSI Manager 4.3 are supported with the following limitations:

Original SCSI Manager:

SCSIReset will not reset the SCSI bus.

The values returned from SCSIStat provide only an approximate indication of what is going on during a transaction. Code that relies on SCSIStat to control an operation may fail.

SCSI Manager 4.3:

MacOS.app does not support Mac OS drivers for third-party SCSI cards. Mac OS X Server DriverKit drivers are required to use these cards.

The SCSIBusInquiry function does not return complete information about each SCSI bus.

The SCSIResetBus function will not reset the SCSI bus.

Command queuing functions, such as scsiQEnable, scsiSIMQHead, scsiSIMQFreeze, scsiSIMQNoFreeze, scsiSIMQFrozen and SCSIReleaseQ are not implemented.

All SCSI transfers use DMA. Handshaking information is ignored. The scsiSelectTimeout parameter is ignored.

SCSIAbortCommand and SCSITerminateIO are not implemented.

The SCSI implementation will attempt to negotiate synchronous data transfer and device disconnect by default.

scsiNoParityCheck, scsiDisableSelectWAtn, scsiSavePtrOnDisconnect, scsiDisableWide, scsiInitiateWide, and scsiRenegotiateSense, scsiNoBucketIn, and scsiNoBucketOut are not supported.

If an application traverses the SCSI chain, devices that are already reserved or in use (e.g., by Mac OS X Server) will not be found. In order to have an application recognize a device via the SCSI manager, you must explicitly set that device to SCSI mode as described below.

Disk Access Modes

The sections below describe the tradeoffs among the three access modes: Shared, Exclusive, and SCSI. If you are just running Mac OS productivity applications, you should not need to switch the access mode for any of your disks or partitions. However, in case you need to run disk utilities - such as Disk First Aid, Disk Copy, or Drive Setup - you may need to (temporarily) switch the access mode of one or more of your disks or partitions. The "Blue Volume Mount Options" control panel is provided to allow you to set these access modes for individual disks and disk partitions. It is described below, after the explanations of the three access modes.

You can determine in which mode a volume is being accessed by selecting it in the Finder and invoking the "Get Info" command from the "File" menu. The dialog that appears includes a "Where" string that describes the mode in which the underlying disk is currently being accessed, along with an indication of the physical disk to which it corresponds. Disks accessed in Shared mode will have "Shared" in this string. Similarly, disks accessed in Exclusive mode will have "Exclusive" in this string. Disk image files (which are always accessed in Exclusive mode) will list the pathname of the disk image file. Disks accessed in SCSI mode will have a string identical to the one they would display if running native Mac OS; typically this string gives the SCSI Bus number and SCSI device ID of the drive.

For disks accessed in Shared or Exclusive mode, the SCSI bus and ID (or ATA/IDE ID) are not given; instead, they are identified in the "Where" string by their Mac OS X Server device name. In order to understand how Mac OS X Server names disk devices, you will need to consult the documentation for Mac OS X Server. Briefly, SCSI (and ATAPI) disks have names like "sd0", "sd1", etc. ATA/IDE drives have names like "hd0"; and floppy disks have names like "fd0". Disk devices may also have more than one HFS(+) partition; the first HFS(+) partition of "sd0" is "sd0_hfs_a", the second is "sd0_hfs_b", etc. Disks without partition maps (such as floppies and ISO9660 CD-ROMs) are treated as though they consisted of a single HFS(+) partition, comprising the whole disk (e.g., "sd0_hfs_a").

Shared Mode

MacOS.app supports mounting HFS(+) volume(s) which are already mounted by Mac OS X Server. This mode of access is called Shared mode because all the files and folders on Shared volumes are simultaneously accessible from Mac OS applications running inside MacOS.app and Mac OS X Server applications running outside of it. Shared mode was chosen as the default file system access mode because it does not require the user to unmount a volume from one environment before mounting it in the other.

Although Shared mode access provides the highest level of interoperability between Mac OS and Mac OS X Server applications, it is not compatible with Mac OS applications that require low-level disk access. Mac OS productivity applications are not affected by this incompatibility since they access files and folders via the high-level interface provided by the File Manager. On the other hand, disk utility programs typically require low-level disk access. Examples of disk utilities that require Exclusive mode access are Disk First Aid, and Norton Disk Doctor. Examples of disk utilities that require SCSI mode access are Drive Setup, and FWB's Hard Disk Toolkit. None of these utilities will function correctly on a volume accessed in Shared mode.

Volumes accessed via Shared mode are slightly less compatible with Mac OS applications than if they were mounted in Exclusive or SCSI mode. But they are far more flexible because they allow you to concurrently share data between Mac OS applications running inside MacOS.app and Mac OS X Server applications running in the Mac OS X Server environment. This means that the files and folders you see in MacOS.app can also be seen from Mac OS X Server.

In Shared mode you should be able to run nearly all of the applications you run on a native Mac OS system. One small difference between volumes accessed via Shared mode is that the size of the underlying "disk" may not be reported accurately. For small HFS disks (like floppies), it might be overestimated by a few kilobytes and for large HFS+ disks (like multi-gigabyte hard drives) it might be underestimated by a few megabytes. This cosmetic difference should not have any adverse affect, since block-level access is not permitted on disks accessed via Shared mode.

In general, other incompatibilities and inconsistencies result from conflicts over shared resources. For example, if a Mac OS application running inside MacOS.app is accessing a file (or group of files) at the same time that a Mac OS X Server application is accessing them, there is a risk that they might make conflicting changes.

One place where this arises is in the process by which the Mac OS Finder rebuilds the Desktop Database. In Mac OS X Server, the Desktop Database is a shared resource that is managed by an independent server task (the "DesktopDB" server) and which fields requests from various clients, including MacOS.app. This works well and provides a centralized place for serializing access to the shared Desktop Database files. However the mechanism used by the Mac OS Finder for rebuilding the Desktop Database conflicts with the Desktop Database server. Consequently, rebuilding the Desktop Database on a Shared volume will not always have the desired effect. This problem will be addressed in a future Finder and MacOS.app. As a workaround you can switch the disk to Exclusive mode, rebuild the Desktop Database, and then switch the disk back to Shared mode. See the section on the "Blue Volume Mount Options" control panel for information on switching modes.

Another example of a shared resource conflict can be seen when attempting to eject a disk from one environment (the Workspace or the Finder) while it is in use by an application in the other environment. In this case, the ejection attempt may appear to succeed (i.e., the volume's icon may disappear from the desktop) but the disk might not be physically ejected from the disk drive. If this happens, the solution is to switch to the other environment and eject the disk from that environment as well (after closing any files that may be in use first, of course). Since Mac OS X Server cannot tell if individual files are open by Mac OS applications running inside MacOS.app, the Workspace will refuse to eject a disk that is mounted in MacOS.app, even if there are no individual files opened from that volume by Mac OS applications. Going in the other direction is a little better; when you attempt to eject a removable disk from MacOS.app it will ask the Workspace to unmount any volumes mounted from that disk and to eject the disk. If there are no files open from that volume and no processes whose current working directory is set to a directory on that volume, then the disk will be automatically unmounted from Workspace and ejected - there will be no need to switch to the Workspace and eject the disk again.

Remember, having a Mac OS X Server application with its "current working directory" set to a folder on a disk marks that disk as "in use" the same way that having an open file does. For example, if you insert a floppy in the Workspace then in a Terminal window "cd" to some directory within the floppy, you will not be able to eject that floppy via MacOS.app.

Removable disks accessed via Shared mode are not ejected upon shutdown of MacOS.app (floppies are an exception).

How does Shared volume support work? MacOS.app contains the same File Manager code used by the native Mac OS with the addition of some logic that determines when a file system request is targeting an object on a Shared volume. These requests are passed over to the HFS(+) implementation in Mac OS X Server. The important thing to note is that this processing happens at the level of Mac OS File Manager requests, as opposed to disk driver requests or SCSI Manager requests. Thus, when you ask to "open" a file on a Shared volume, that request is sent to Mac OS X Server and is processed there. The results of the "open" in Mac OS X Server are passed back to MacOS.app and mapped into Mac OS "open" results. Then, a "read" from the newly opened file would be mapped into a Mac OS X Server "read" request and the results mapped in a Mac OS "read" result. The MacOS.app implementation of the

Shared file system tries to map the file system requests and their results as closely as possible to native Mac OS. Applications should never know (or care) that they are running in the MacOS.app on a Shared volume, as long as they limit themselves to making File Manager requests and do not attempt to make disk driver or SCSI Manager requests.

The choice between Shared and Exclusive mode access can be made on a per-partition basis for disks with multiple HFS(+) partitions.

Exclusive Mode

MacOS.app supports mounting HFS(+) disk volumes in a mode that permits block-level access. This mode permits certain disk utilities (such as Disk First Aid and some operations in Disk Copy) to run that would not work with a disk accessed via Shared mode. This is called Exclusive mode because disks accessed by MacOS.app in this mode appear exclusively in MacOS.app and cannot be accessed by Mac OS X Server applications. You can request that a disk or partition be accessed via Exclusive mode by using the "Blue Volume Mount Options" control panel.

When Mac OS X Server first detects an HFS(+) disk partition (either when starting up or when a removable disk is inserted into a drive) it mounts it and notifies MacOS.app. MacOS.app is also notified about disks that are not recognized or mounted by Mac OS X Server. When MacOS.app notices a disk that has been mounted in Mac OS X Server for which the user has selected Exclusive mode, it asks Mac OS X Server to unmount the disk and then mounts it exclusively.

Because it remains under the control of the Mac OS X Server SCSI drivers, a disk accessed via Exclusive mode cannot be accessed via the Mac OS SCSI Manager, even if the underlying disk is a SCSI disk.

Volumes accessed in Exclusive mode can be read from and written to, regardless of the access rights of the user.

Disk image files like the supplied StartupDisk.img are always accessed via Exclusive mode.

The choice between Exclusive and Shared mode access can be made on a per-partition basis for disks with multiple HFS(+) partitions.

Removable disks accessed via Exclusive mode are usually ejected upon Shutdown or Restart of MacOS.app. CD-ROMs are an exception and are not ejected upon shutdown, in order to more closely mimic the behavior of Mac OS.

SCSI Mode

MacOS.app supports SCSI disk devices that are recognized by Mac OS X Server. MacOS.app provides a special compatibility mode for accessing these devices via the SCSI Manager, just as they would be accessed under the native Mac OS. This mode provides the highest level of compatibility with Mac OS disk utilities, especially with those that require SCSI access, like Drive Setup.

Like Exclusive mode, SCSI mode must be selected by using the "Blue Volume Mount Options" control panel. When MacOS.app first detects a disk for which SCSI mode has been selected, it attempts to unmount it from Mac OS X Server. If this succeeds, MacOS.app can access it in SCSI mode without fear of interference from Mac OS X Server applications.

Volumes accessed in SCSI mode can be read from and written to, regardless of the access rights of the user.

Unlike the choice between Shared and Exclusive mode access - which can be made on a per-partition basis for disks with multiple HFS(+) partitions - accessing a disk via SCSI mode precludes any other sort of access, either by Mac OS X Server or via Shared or Exclusive mode in MacOS.app. One consequence of this is that a disk containing a UFS file system partition that is mounted by Mac OS X Server cannot be accessed via SCSI mode in MacOS.app. For example, if your system has only one hard drive and has separate partitions for UFS and HFS(+) file systems, you will not be able to access the disk in SCSI mode.

Removable SCSI drives without media present will become reserved for SCSI mode access if probed via a SCSI disk utility like Drive Setup.

SCSI mode access is not available for ATAPI devices (which includes the internal CD-ROM and optional Zip drive on some Power Macintosh G3 models) or IDE/ATA devices (which include the internal disks on most non-Server Power Macintosh G3 models).

Switching Modes: The "Blue Volume Mount Options" Control Panel

In the "Apple Extras" folder of the supplied StartupDisk.img is the control panel to set the desired access mode for disks and disk partitions. Disks can be accessed in one of three modes (Shared, Exclusive, or SCSI), although not all disks will permit access in SCSI mode. A disk cannot be accessed in SCSI mode if it is not a SCSI disk (e.g., floppies, ATA/IDE/ATAPI disks). Nor can it be accessed in SCSI mode if there is a UFS file system mount point active on the disk at the time the mode switch is attempted (either when the control panel is launched or when MacOS.app is starting up).

Launching the "Blue Volume Mount Options" control panel displays a single dialog which can be dismissed by quitting the control panel or closing the window. Any changes that are made are stored immediately upon quitting the control panel, although most changes do not take effect until MacOS.app is restarted.

The control panel lists all the disk drives and disk partitions that it finds on the system, together with three columns of radio buttons, named after the three possible modes of operation: SCSI, Exclusive, and Shared. If a radio button does not appear in one of the columns, it means that the corresponding mode is not available for that drive (e.g., SCSI mode for an ATAPI CD-ROM drive). Radio buttons are used to convey the fact that each drive or partition can only be accessed in one mode at a time. For a brief explanation of how Mac OS X Server names disk devices, see the beginning of the "Disk Access Modes" section. If a disk partition is already mounted in Shared or Exclusive mode, it will appear in the control panel under that name (e.g., "sd0_hfs_a"). If it is a removable drive with no disk present, it will appear under the name of the drive (e.g., "sd0"). Finally, if it is being accessed via SCSI mode, it will appear labeled with its SCSI Bus and device ID (e.g., "Bus 0, ID 0"). In each case, these labels should correspond closely to what you will find in the "Where" string displayed in the Finder's "Get Info" dialog for that volume.

The same disk may appear under different names at different times in the "Blue Volume Mount Options" control panel depending on whether there is a disk in the drive. For example, the internal ATAPI CD-ROM drive on a Power Macintosh G3 will appear as "ATA drive sd0" when there is no CD-ROM in the drive, but as "HFS partition sd0_hfs_a" when a CD-ROM is in the drive.

If a disk has multiple HFS(+) partitions, they can be accessed in Shared or Exclusive mode independently from one another. In other words, the choice between Shared and Exclusive mode can be made on a per-partition basis. Similarly, Mac OS X Server can mount a UFS partition from a disk containing one or more HFS(+) partitions, each of which may be accessed in Shared or Exclusive mode. SCSI mode is different, though, because it requires complete control of all requests going to the disk. Therefore, selecting SCSI mode for one partition on a disk causes all the partitions on the disk to be accessed via SCSI mode. If you try this, you will see that the settings of the radio buttons automatically reflect this constraint. Similarly, you cannot select SCSI mode for a disk containing a mounted UFS file system. If you do select SCSI disk mode for a disk that contains an unmounted UFS file system, your selection will be honored. You will not be able to mount that UFS file system in Mac OS X Server while MacOS.app is accessing the disk in SCSI mode.

For fixed, non-removable disks, changes made via the "Blue Volume Mount Options" control panel will not take effect until MacOS.app is restarted. Removable disks are an exception to this rule: if you change the access mode for a removable disk then it will be accessed in that mode the next time you insert a disk in the drive. Consequently, you can quickly change the access mode for a removable disk by changing the setting in the control panel (and quitting it), ejecting the disk, and reinserting it - all without needing to restart MacOS.app.

There is one situation in which switching modes requires special care. When switching a non-removable disk to Shared mode from some other mode, you must shut down MacOS.app and wait for the Workspace to remount the disk on its desktop before re-launching MacOS.app. Otherwise, if you were to switch a disk to Shared mode and restart MacOS.app (e.g., from the Finder) then the Workspace might not have enough time to remount the disk before MacOS.app claimed it in Exclusive mode again. In this situation, the disk would not appear on the desktop of the Workspace and the "Where" string in the Finder's "Get Info" dialog for the disk would indicate "Exclusive". If this happens, the only way to get the Workspace to remount the disk for Shared access is to log out of the Workspace (after shutting down MacOS.app) and log back in again.

Currently, settings made via the "Blue Volume Mount Options" control panel are stored in the user's defaults database, although this might change in the future. Consequently, in a NetInfo environment, the same settings will be used for a user regardless of the machine they login to - beware. To see which disks have been set up in Exclusive mode, execute this command from the command line (i.e., in a Terminal window): "defaults read MacOS ExclusiveDisks". This "defaults" setting is a list consisting of device and/or individual partition names, separated by spaces. To see which disks have been set up in SCSI mode, execute this command at the command line: "defaults read MacOS SCSIDiskLoans". This list consists of ":" pairs, separated by spaces. If a disk or partition is not mentioned on either of these lists then MacOS.app will attempt to access it via Shared mode. In general, there should be no need to view these settings from the Mac OS X Server command line rather than with the "Blue Volume Mount Options" control panel. However, this information is provided because it might be useful for remote diagnosis and trouble-shooting.

The disk mode selections made via the "Blue Volume Mount Options" control panel are only requests. In some cases, it might not be possible to honor them and MacOS.app may mount a disk in a mode other than the one selected in the control panel. To find out what mode a volume is being accessed in, you can interpret the "Where" string displayed in the Finder's "Get Info" dialog for that volume, as described at the beginning of the "Disk Access Modes" section. For example, if Exclusive mode is selected for a disk partition but a Mac OS X Server application has a file from that partition open, then MacOS.app will not be able to get Exclusive access when it starts up. Rather than having the disk not appear in MacOS.app in this situation, MacOS.app will fall back to mounting the disk in Shared mode.

Mac OS X "Disk Mounting" Preferences

There is a preference setting, "Disk Mounting", which can restrict MacOS.app's ability to unmount volumes from Mac OS X Server. In turn, this can prevent MacOS.app from ejecting removable disks and from accessing disks via Exclusive or SCSI mode.

To invoke the "Disk Mounting" preference panel, select it in the "Computer Settings" submenu of the Mac OS X Server Apple Menu. The panel includes some explanatory text. To change the panel's setting, you must be logged-in as root. Changes will not take effect until Mac OS X Server is restarted.

The default setting for a Server configuration is either "Fixed & removable disks" or "Only fixed disks". In a non-Server configuration where MacOS.app is going to be used extensively, it may be more convenient to select the "Only the startup disk" setting, for reasons that will be explained. However, this setting is not appropriate for a Server, because it means that files cannot be served from disks other than the startup disk unless someone is logged into the server. The other two settings are more appropriate for a Server because they permit files to be served from all disks attached at startup time, regardless of whether anyone is logged into the server.

In either of the Server modes you must be logged-in as root if you wish to use MacOS.app to eject removable disks or access disks via Exclusive or SCSI mode. This is a security precaution that is appropriate for a Server configuration, but might be overly restrictive for a Macintosh that is being used as a personal workstation, especially if it is shared between non-root users. If you select the "Only the startup disk" setting in the "Disk Mounting" preference panel (and restart Mac OS X Server), then disks other than the startup disk will be mounted upon login and unmount upon logout. As a result, the user that logs in will be able to use MacOS.app to unmount these disks, e.g. in order to eject a removable disk or to access a disk via Exclusive or SCSI mode.

Disk Drive Support

The following sections discuss the level of support provided for various kinds of disk media. Since some things apply to whole families of drives (e.g., SCSI drives) and some things apply to specific kinds of drives (e.g., CD-ROM drives), there is some overlap between the categories and you may need to read them all in order to find what you are looking for.

SCSI Disk Drives

SCSI disk drives can be accessed in Shared, Exclusive, or SCSI mode.

For more information on SCSI mode file system access, see the section on "SCSI Mode File System Access". For more information on switching the access mode, see the section on the "Blue Volume Mount Options" control panel.

SCSI disk devices (e.g., hard drives, CD-ROM drives, Zip drives, and Jaz drives) are supported, including those with multiple partitions. In Shared and Exclusive mode they behave like generic SCSI hard drives with the addition that disk-insertion detection and auto-ejection are supported. In Shared and Exclusive mode, special vendor-specific drivers (e.g., the Iomega Driver) are not loaded or used. If the drive has a manual-ejection button then it will be disabled while the disk is being accessed.

In SCSI mode, most third-party SCSI drivers are supported, including those that make possible special device-specific features (e.g., hardware write-protection or password protection). In this mode, MacOS.app supports the original SCSI Manager and SCSI Manager 4.3 with limitations. See the section on "Bugs and Compatibility Issues" for more details.

Mac OS X Server implements SCSI device arbitration. This means that only one client can send SCSI commands to a SCSI device at a time. Often, in the case of SCSI disks, this client is the Mac OS X Server file system. When

MacOS.app is accessing a disk partition in Exclusive mode, then it is the client. For the purpose of SCSI mode access, MacOS.app can "see" any SCSI device not in use by Mac OS X Server (or any other client). In particular, removable disk drives with no media in place are always visible to MacOS.app and if probed will be accessed in SCSI mode until MacOS.app is shut down.

ATA/IDE/ATAPI Disk Drives

ATA/IDE/ATAPI drives can be accessed via Shared or Exclusive mode. They cannot be accessed via SCSI mode.

"ATA" and "IDE" are used interchangeably. The internal hard drives on most non-Server Power Macintosh G3 models are ATA/IDE drives. MacOS.app does not currently support the Mac OS ATA Manager. A future release may include an "ATA mode" similar to the existing "SCSI mode". "ATAPI" drives are special ATA/IDE drives with additional features. The internal CD-ROM and optional Zip drives on Power Macintosh G3 models are ATAPI drives.

Floppy Drives

Floppy drives can be accessed in Shared or Exclusive mode. They cannot be accessed in SCSI mode.

High Density (1.44 MB) floppies are fully supported. 800 KB floppies are supported read-only.

MacOS.app supports auto-detection and auto-ejection of floppies. Low-level initialization is only supported in Exclusive mode. If you insert a floppy that lacks a low-level format, it will be automatically accessed in Exclusive mode in order to permit you to initialize it. If, after initializing such a floppy, you wish to access it in Shared mode, you will need to eject it and reinsert it. See the section on the "Blue Volume Mount Options" control panel for instructions on how to change the mode. See the "Bugs and Compatibility Issues" section for other floppy issues.

Disk Image Files

Disk image files are volume images in Mac OS Disk Copy uncompressed format, stored in Mac OS X Server's UFS file system. They are always accessed in Exclusive mode. From the Mac OS X Server environment, they appear as large binary files whose name end in ".img". In the Mac OS environment, however, they appear as regular Mac OS volumes (with a special icon). By default, MacOS.app will startup from the disk image file in /Local/Library/MacOS/Users//StartupDisk.img. See the section "Working With Disk Image Files", below, for details.

CD-ROMs

CD-ROMs are supported in MacOS.app. They behave like locked SCSI hard drives when accessed via Shared or Exclusive mode. MacOS.app supports auto-detection and auto-ejection of CD-ROMs.

HFS(+) CDs can be accessed in Shared, Exclusive, or SCSI mode. DOS, ProDOS, PhotoCD, ISO 9660, and High Sierra CDs are automatically mounted in Exclusive mode, even if Shared mode is selected. They are also accessible in SCSI mode.

ISO9660 CDs are treated specially: they are mounted simultaneously in Mac OS X Server and in MacOS.app, but they are mounted in Exclusive mode in both environments. This may sound like a contradiction, but is possible because CD-ROMs are read-only media and there is no risk of writing inconsistent data or causing disk corruption. ISO9660 CD-ROMs are the only exception to the rule that disks appearing in MacOS.app in Exclusive mode do not appear in Mac OS X Server.

Only the first session of a multisession CD-ROM will be accessible in Shared or Exclusive mode. To access additional sessions the CD-ROM drive must be accessed in SCSI mode. See the section on the "Blue Volume Mount Options" control panel for instructions on how to change the mode.

Audio CDs are only accessible in SCSI mode. Audio playthrough is not supported, however.

If an Audio CD or any other CD in an unsupported format is inserted in Shared or Exclusive mode then the CD will automatically be ejected from the drive.

CD-ROMs are not ejected upon Shutdown or Restart of MacOS.app, even if accessed via Exclusive mode. This mimics the behavior of the native Mac OS.

DVD ROMs

DVD ROM disks are supported in Exclusive and SCSI modes. MacOS.app supports the UDF file system format that is used on these disks. DVD ROM movie playback is not supported in Mac OS X Server.

Working with Disk Image Files

Use of Disk Image Files

Although disk image files are used as default startup volumes in this release, they may not be the best choice for long-term use. More convenient startup volume options are available in this release which supports HFS(+) volumes that can be shared between Mac OS X Server and Mac OS.

You can use the Mac OS Startup Disk control panel to select a different startup volume. This can be very useful, but a few important steps are needed to properly setup a startup volume. If you plan to use this feature, be sure to read the "Startup Options" section below.

The StartupDisk.img created when you first launch MacOS.app is a relatively small startup volume (215 MB), which will not allow installing much software. It is suggested that you use available Mac OS partitions or create additional disk images to hold Mac OS applications and documents.

Even if you install applications elsewhere, as suggested, many applications also take up space in the System Folder on the startup disk. Enough free space (about 40 MB) has been left for the System Folder additions of a few applications. However, you may eventually run out and be forced to enlarge your StartupDisk.img, as described below, or switch to startup from an HFS(+) partition.

Creating New Disk Image Files

At startup time, after finding the startup volume (StartupDisk.img by default), MacOS.app will search for and attempt to mount image files (files ending in ".img", but excluding StartupDisk.img) in the following Mac OS X Server directories:

```
/Local/Library/MacOS/Users/<user name>

~/Library/MacOS

/Local/Library/MacOS

/System/Library/MacOS
```

Note that the first two directories are private to a particular user ("~" means the current user's home directory), whereas the last two are global to all users of the machine.

MacOS.app respects the file permissions for disk images. If the user has only read permissions for the disk image file in the Mac OS X Server file system, then the image will appear locked in MacOS.app.

You can create new disk image files in Mac OS X Server by using Disk Copy in MacOS.app and creating the disk image on a shared volume, which can then be moved to one of the above directories. You can also create a disk image on a native Mac OS system and transfer the file to Mac OS X Server with "ftp" (or other utility).

Alternatively, you can use the provided "createimage" tool in the /usr/bin/ directory. It creates an empty image file that can be made available within MacOS.app. To use this tool, from a Terminal window (when logged in as the user who intends to use the image), execute:

```
createimage -mb num -o name
```

where "num" is the desired disk image size in MB and "name" is the pathname of the image file to be created, usually of the form:

```
"/Local/Library/MacOS/Users/<user name>/<name>.img".
```

For example:

```
createimage -mb 100 -o /Local/Library/MacOS/Users/me/mydata.img
```

The next time MacOS.app is started, Mac OS will present a dialog offering to initialize this new volume; you should allow the initialization to proceed.

Enlarging Your Startup Disk Image File

You can enlarge your StartupDisk.img by creating a new disk image with "createimage," and copying the contents of the startup disk to that new image. Perform the following steps to create a larger startup disk.

1. Make sure that MacOS.app is not running.
2. Create a new, larger, disk image using "createimage".

```
cd /Local/Library/MacOS/Users/<user name>

createimage -mb <size in MB> -o NewStartupDisk.img
```

3. Start MacOS.app.
4. Initialize the new volume when asked.
5. Copy the contents of the startup disk to the new volume.
6. Shut down MacOS.app.
7. Rename the original StartupDisk.img and rename your new disk image.

```
cd /Local/Library/MacOS/Users/<user name>

mv StartupDisk.img StartupDisk.img.old

mv NewStartupDisk.img StartupDisk.img
```

MacOS.app will now startup from your newly created startup disk.

When you are satisfied that the new startup disk image is OK, the old image may be removed to conserve disk space.

It is also possible to transfer image files to native Mac OS and modify their contents using Apple's Disk Copy utility. The correct file type and creator for image files are 'hdrv' and 'ddsk', respectively. These can be set when transferring if using Fetch, or afterwards via ResEdit or other utilities. The version of Disk Copy included with this release of MacOS.app supports opening disk image files with incorrect file types via drag and drop. Disk Copy will treat the data fork as a valid image only if the resource fork does not have any of the NDIF specific resources in it (or if there is no resource fork at all). So, if ftp is used to download just the data fork of a Disk Copy image file, Disk Copy should be able to mount it.

Startup Options

Startup

By default, MacOS.app starts up from your StartupDisk.img. If you have problems with your StartupDisk.img, see the section "Startup Disk Problems", below. If the currently selected Startup volume for MacOS.app does not support MacOS.app, a new StartupDisk.img will be created to allow proper startup.

If you wish, you may select an HFS(+) partition as your startup disk, using the Startup Disk control panel. You can even dual boot native Mac OS and MacOS.app from the same startup disk.

As with native Mac OS systems, you can hold the "C" key down to start up from the CD-ROM drive. This is done just after starting up MacOS.app, but before the gray screen appears.

Configuring a Startup Disk's System Folder

For versions of Mac OS prior to Mac OS 8.6 installation requires that the target disk be in Exclusive mode during installation. Beginning with Mac OS 8.6 it is possible to perform an installation to a target disk in Shared mode as well.

Once your new startup disk is set up, select it using the Startup Disk control panel and then restart MacOS.app.

After setting your system to start up from a Mac OS partition, you may remove the StartupDisk.img file from the /Local/Library/MacOS/Users/ directory.

Startup Problems

If MacOS.app immediately quits on a user's first attempt to start up, check the ownership of the /Local/Library/MacOS/Users/ directory. If it is owned by root, change the ownership to using the chown command, then restart MacOS.app.

Startup Disk Problems

If you have a problem with your StartupDisk.img, MacOS.app can be forced to install a new StartupDisk.img. When starting MacOS.app, hold down the Command-Option-Shift keys. You will be given the option to modify your PRAM file. You must modify your PRAM file to proceed with fixing your startup disk problems. If you accidentally pressed the Command-Option-Shift keys, you should choose the Quit option.

After modifying your PRAM file, you will be given the option of deleting, using or renaming your current StartupDisk.img. If the disk image is corrupted and you don't want to mount it, but you don't want to delete it, be sure to remove the ".img" extension when renaming. Renaming a disk image across Mac OS X Server file system volumes (mount points) will result in a copy (rather than a rename). This will take a while.

If the "Copying StartupDisk.img" dialog is cancelled when MacOS.app is not in the foreground (i.e., the dialog is frontmost, but is not active), the "Cancel" button may appear pressed, but then doesn't release. Click anywhere in the dialog to complete the cancel operation.

Renaming a startup disk image across file system volumes when there is insufficient disk space available may cause Mac OS X Server to fail. Due to the large size of the disk images, caution should be used when maintaining several on your disks.

Copying StartupDisk.img Problems

If you receive the "Helper Copy Problem. Exception raised during the write." alert while copying the StartupDisk.img, verify that there is sufficient disk space available for the copy (~ 225 M). This alert can be received if there is negative space available as reported by "df". As a non-root user, type "df -kl" in a Terminal window to get this information.

Bugs and Compatibility Issues

Killing MacOS.app from Mac OS X Server Workspace Process Menu

If you use the Mac OS X Server Workspace process menu to force-kill MacOS.app, a problem occurs if MacOS.app has gone through a restart since being launched by the Workspace. The problem occurs because whenever MacOS.app goes through a restart it gets different process IDs for all of the processes associated with MacOS.app. The force-kill option will shut down all of the MacOS.app windows, but the MacOS.app processes will not be killed because the kill signal will be sent to the original process IDs which no longer correspond to the running MacOS.app processes. Therefore, it will appear that MacOS.app has been killed, but you will not be able to launch a new MacOS.app. To work around this problem, you must manually kill the old MacOS.app processes from the command line using the kill command. You must first find the process ID of MacOS.app. You can do this by typing the following command from the command line:

```
ps -aux | grep MacOS
```

This will produce output that looks something like this:

```
machine ps -aux | grep MacOS

user 721 96.5 26.1 1.03G 33.4M ? R N 2:21 MacOS.app

user 752 0.2 0.1 924K 88K p1 U 0:00 grep MacOS
```

This output shows that the process ID for MacOS.app is 721 and the process ID for the grep command you just ran is 752. You must now kill the MacOS.app process by entering the following command (substitute the process ID of the MacOS.app process you are trying to kill for the process ID 721 as shown below):

```
kill -9 721
```

After killing the MacOS.app process in this way, you should be able to launch a new MacOS.app from the Workspace.

Tear Off Application Menu

The Mac OS Applications window that appears when the Applications menu is "torn off" does not list any Mac OS X Server applications that normally appear in the MacOS.app Applications menu. To switch from MacOS.app to another Mac OS X Server application, you must use the Applications menu and not the tear-off window.

AppleShare File Server connection lost using TCP/IP

When running MacOS.app using Mac OS System 8.5, there is a problem that may cause loss of connection to AppleShare File Servers that are connected via TCP/IP. The workaround for this problem is to connect to the server using the AppleTalk protocol instead. To do this, when selecting the File Server using the Chooser, hold down the Option key when you click on the OK button. This forces the system to connect via AppleTalk and not TCP/IP. This problem has been corrected in Mac OS System 8.6 which is the version that ships with MacOS.app.

Unable to read PC Zip disks

The present version of Mac OS X Server is unable to read PC Zip disks that have been formatted using the Iomega Tools. The problem does not occur if you initialize the Zip disk using MacOS.app by accessing the Zip drive using Exclusive mode and then initializing it by selecting the Finder's "Erase Disk" menu item.

Launching PowerPC Applications from Disks in Direct SCSI Mode

There is a problem that occasionally occurs when launching PowerPC Macintosh applications from disks accessed via direct SCSI mode. The problem causes MacOS.app to hang because of repeated timeouts attempting to access the disk. If you encounter this problem try changing the disk access to Exclusive mode. See the "Disk Access Modes" section for more details.

Symantec's ACT!

When running MacOS.app using Mac OS System 8.5, Symantec_s ACT! will not run properly in MacOS.app. This problem has been fixed in Mac OS System 8.6 which is the version that ships with this release of MacOS.app.

Eudora Pro 4.1

When running this version of Eudora Pro on MacOS.app, the application crashes because it is making a power manager call which is not implemented in MacOS.app. A future version of Eudora Pro will correct this problem.

MacBench 5.0

When running the MacBench 5.0 "all" test (with CD in), MacOS.app will crash when it arrives at the Microsoft Word formatting stage. This problem is currently under investigation and should be corrected in a future version of MacOS.app.

Myth II

When launching Myth II under MacOS.app you may receive an error dialog saying "Myth does not have enough free memory to launch. Try closing open applications or turning on VM". This message is incorrect; the actual problem is due to the Myth application attempting to perform a dynamic screen resolution change that is not supported in MacOS.app. In order to run Myth II under MacOS.app you must first change the screen resolution in Mac OS X Server to 640x480 using the Preferences.app application, then launch MacOS.app with the new screen resolution and Myth II will run correctly.

Switching from MacOS.app to Mac OS X Server

Switching from MacOS.app to Mac OS X Server using command-return is not allowed during startup of MacOS.app. Attempts to do so prior to the Finder starting up will be ignored.

Locked files not owned by current user

MacOS.app runs the MacOS in a multiuser environment. Native MacOS runs in a single user environment. In the Mac OS X Server environment a user must be the owner of a file in order to unlock it. If you try to move a locked file or delete a locked file, owned by someone else in the underlying file system, you will get an "access privileges" error. You can workaround this limitation in several ways. 1) use the chown command to change the owner of the file 2) shutdown MacOS.app and login to the system as the owner of the file, then start up MacOS.app again 3) do the move/rename in a terminal window as root or after doing a su to the owner of the file.

Disk Icons

Disks formatted with 3rd party utilities and utilizing 3rd party drivers may appear on the desktop with a different icon than they would under the native Mac OS. For example, a removable Zip or Jaz disk may appear on the desktop as a generic hard drive icon.

Disk First Aid

The version of Disk First Aid currently shipping will not function correctly when its target is a disk accessed via Shared mode. You can run the Mac OS X version of Disk First Aid (DiskFirstAid.app) or you can set the access mode of the target disk to Exclusive mode. See the "Disk Access Modes" section for more information.

Desktop Rebuild For Shared Mode Volumes

Desktop rebuilds on some volumes mounted in shared mode may take longer than the same rebuilds in native MacOS. It is recommended that if you must rebuild your DesktopDB, you do it in native MacOS or in MacOS.app using Exclusive mode. In fact, a rebuild of the DesktopDB in shared mode does not actually delete the old DesktopDB files (although it appears from the progress dialog that it does), so repair of any damaged entries may not be as complete as would be the case in Exclusive mode or in Native Mac OS.

MacOS Crashes After Improper Shutdown

There is a problem that only happens when running with Mac OS System 8.5 or 8.5.1, in which MacOS.app crashes on startup after being improperly shut down. This is a side effect of putting up the "Your Macintosh was improperly shut down" dialog and will be fixed in a future release of Mac OS. The workaround to this problem is to uncheck the "Shut Down Warning" checkbox in the General Controls control panel. Note that if you do this, not only will there no longer be a warning dialog after crashes, but Disk First Aid will not be automatically run in such cases. You should run Disk First Aid to check the integrity of your file system after all improper shutdowns. There is a Mac OS X Server version of Disk First Aid (DiskFirstAid.app) that can be run on volumes shared with Mac OS X Server. In order for Disk First Aid in MacOS.app to run on a volume, it must be mounted in "Exclusive" mode (see the Disk Access Modes section). Or you can boot into native Mac OS and run Disk First Aid on the volume in question.

Runtime Performance

The runtime performance of MacOS.app is sensitive to other processes running on the Mac OS X Server, especially if these other processes consume the majority of "CPU" time. These types of processes are known as "CPU-bound" or "CPU-intensive" processes. The runtime performance of MacOS.app is highest when these types of processes are not running in Mac OS X Server.

File System Performance

In this release, Shared disk mode may be slower than other modes for some operations. If this is a concern, consider switching disk access modes or using disk images (which are always accessed in Exclusive mode). Disk access modes are discussed in detail in the "Disk Access Modes" section. Shared mode performance is expected to improve significantly in future releases.

NMI (Non-Maskable Interrupt)

On native Mac OS, using Command-Power to generate a NMI invokes the installed debugger (MacsBug) or invokes MicroBug if no debugger is installed. MicroBug is not currently supported in MacOS.app, so Command-Power with no debugger installed is ignored. When a debugger is installed, you may occasionally have to use Command-Power more than once to invoke the debugger. A current version of MacsBug is provided in the Apple Extras folder. Older versions are not compatible.

Mac OS X Server Workspace Logout

When logging out of Mac OS X Server with MacOS.app running, MacOS.app will come to the foreground with a dialog informing the user of the steps to safely shut down MacOS.app. The Workspace logout will be stopped. Upon shut down of MacOS.app, the user will again have to select Logout from the Workspace File menu. If MacOS.app was started from a shell window, it is not registered with the Mac OS X Server, so it will simply be killed during the logout process. This is why we don't recommend starting MacOS.app this way. Also note that if MacOS.app has gone through a restart since being launched by the Workspace, the process IDs for MacOS.app will have changed and the Workspace will not be able to contact it to initiate the safe shutdown dialog. This will also result in MacOS.app being killed during the logout process.

Sparse Virtual Memory

If Mac OS X Server runs out of disk space for virtual memory when MacOS.app is trying to allocate sparse virtual memory for an application, Mac OS will likely crash. This problem will be addressed in a future version of Mac OS X Server.

Aliases on Removable Disks

Mac OS has a limitation that sometimes causes aliases created on removable disks to fail when they are taken to a machine other than the one on which they were created. Because running MacOS.app is much like taking your disks created under native Mac OS and moving them to a different machine, this bug may manifest itself even though you did not physically move your disks to a different machine. This problem will be addressed in a future version of Mac OS.

Disk Copy Disk Images

Starting with Disk Copy version 6.3.3, it is possible to mount Disk Copy disk images from a Shared volume. However, it is not possible to create a disk image from an existing disk which is being accessed via Shared mode (i.e., using either of the "Create Image from Folder..." or "Create Image from Disk..." items in the "Image" menu of Disk Copy). If you are using an older version of Disk Copy to mount a disk image, or you are trying to create a disk image file from an existing disk, you will need to set that disk volume to be accessed via Exclusive mode. See the "Disk Access Modes" section for more information.

Disk images will only mount from shared volumes when the new Disk Copy driver (6.3.3) is loaded. This will happen if you run Disk Copy 6.3.3. The newer driver will override older drivers and "stick" until Shutdown once loaded. This does mean that if you mount an SMI (Self Mounting Archive) created with an earlier version of Disk Copy before the new Driver has loaded, it will not work. The workaround is to run Disk Copy 6.3.3 once.

Disk Initialization

There are two kinds of "Disk Initialization": low-level formatting is device-specific and only need to be performed once for the life of the device, whereas high-level formatting simply writes an empty filesystem onto a device that already has a low-level format. The Finder's "Erase disk..." menu option usually only performs a high-level format, except for floppies, where it also causes a low-level format to be performed. The low-level formatting and partitioning of SCSI and ATA/IDE drives is performed by the Drive Setup application.

SCSI mode: The low-level formatting and partitioning of SCSI disks can only be achieved via Drive Setup for disks that are accessed via SCSI mode. Currently, this is not supported for ATA/IDE drives.

Exclusive mode: The Finder's "Erase disk..." menu option should function as expected for all volumes accessed via Exclusive mode. It will even perform a low-level format for floppies, as long as they are accessed via Exclusive mode.

Shared mode: Neither Drive Setup nor the Finder's "Erase disk..." menu option will function for disks accessed via Shared mode. You should not attempt to reformat or erase a volume that is being accessed via Shared mode. If you select a Shared disk and invoke the "Erase disk..." menu option and then select either the "Mac OS Standard" or "Mac OS Extended" format, then the operation will be aborted and you will get an error alert stating that the "Erasing the disk failed!", and the volume will be unmounted causing it to disappear from the desktop. If this happens, you can remount the volume via the Disk First Aid application - no data will be lost or altered.

The mouse cursor may freeze while performing the low-level format portion of the initialization process on a floppy. Switching to Mac OS X Server will be disabled until the formatting has completed, which may take several minutes.

MacOS.app ignores UFS disks by design, so you cannot reinitialize a UFS disk as HFS(+) with MacOS.app. However, you can do this via the native Mac OS.

NFS Sharing of Disk Images

Read-only disk images can be shared via NFS by instances of MacOS.app running on different machines, but read/write images must not be shared or image corruption will result. Note that startup disk images (StartupDisk.img) are always read/write. In the future these rules will be enforced by MacOS.app when NFS advisory locking (rpc.lockd) is available in Mac OS X Server; but for now don't try it. The sharing of all volume types works fine via Personal File Sharing and AppleShare.

Floppy Disk Can Prevent Startup

Floppy drives have traditionally been treated specially in the Mac OS startup process; the Mac OS always looks for a bootable floppy before attempting to start up from the disk chosen via the Startup Disk control panel. Originally, this was done in order to make it possible to start up a Macintosh with a floppy in case of hard disk corruption. Consequently, the Mac OS attempts to eject any non-bootable floppy that it finds in the drive during startup. MacOS.app inherits this behavior, but, unlike the native Mac OS, can be prevented from doing so by Mac OS X Server applications that may have files open on the floppy, not allowing it to be ejected from the drive. If this happens, MacOS.app will be unable to start up. If you would like to share files from a floppy between Mac OS X Server applications and MacOS.app applications, you should insert the floppy after starting up MacOS.app. Alternatively, you could eject it before launching MacOS.app and reinsert it after MacOS.app has started up.

Removable Media - Insertion and Ejection

When inserted, HFS(+) disks may take longer to mount in the Finder if accessed in Exclusive mode rather than in Shared mode. The extra delay results from the fact that HFS(+) disks are automatically mounted by Mac OS X Server and then need to be unmounted on behalf of MacOS.app in preparation for being mounted in Exclusive mode. This extra step essentially doubles the time required to mount a disk and may be noticeable - especially with slow media like floppy disks.

A request to eject a removable disk within MacOS.app may fail silently if the disk is shared with Mac OS X Server and files are open on the Mac OS X Server side (or a process has its current working directory set to a directory on the disk). In this situation, MacOS.app will behave as though the disk had been ejected (e.g., the disk's icon will disappear from the Finder's desktop), but the disk will not have been physically ejected from the drive. In this situation, you will have to switch to Mac OS X Server and eject the disk via the Workspace (after closing any open files, of course).

MacOS.app ejects all removable media upon shutdown if they are accessed via Exclusive mode, with the exception of the CD-ROM drive. If you select a removable disk as the startup disk using the Startup Disk control panel and that disk is accessed via Exclusive mode, then you will have to quickly reinsert the disk into the drive during the restart.

File System Permissions on HFS(+) Volumes

The Mac OS X Server permissions model is enforced on volumes accessed in shared mode. The way permissions are enforced differs for HFS and HFS+ volumes, due to differences in their ability to store permission information. HFS volumes are unable to store permission information and therefore permissions have to be synthesized whenever they are needed. The permissions for the volume's mount point are used as the starting point for this synthesis (with appropriate differences for files versus folders). Moreover, when Mac OS X Server starts up, it mounts local volumes, setting the owner of these volumes to be root and the group to "macos". MacOS.app runs with an effective group id of "macos". By default, the macos group is set up to allow read/write access. Thus any user running MacOS.app will have access to all files and folders on HFS volumes mounted in shared mode.

HFS+ volumes mounted in shared mode behave similarly to HFS volumes with the exception of permissions that are explicitly set. Permissions are saved to disk on HFS+ volumes and are persistent on Mac OS X Server. However, native Mac OS completely ignores the permission information: it is neither enforced nor maintained. The HFS+ volume mount point will be owned by root and the group will be set to "macos", just as with HFS volumes. When a file is created the current user will be owner of the file and the group will be "macos". This will enable users in MacOS.app to access files as if they were running native MacOS. Please note that once permissions are set on HFS+ volumes they are honored when MacOS.app runs. So if you, or someone else, sets permissions in a terminal window, the above mechanism to allow MacOS.app access (via group macos) to files and folders will not allow access for someone without appropriate permissions to a file or folder. Unfortunately, MacOS was not designed to run in an environment where file access permissions might deny access. In most cases volumes mounted in shared mode will return "access denied" error codes that the Finder will pass along to the user when a permissions failure is noticed in the underlying file system. But there may be some cases where a confusing error may occur - so if you see strange error messages or odd behavior from an application on an HFS+ volume mounted in shared mode, keep permissions in mind.

As noted above, the group "macos" is a special group used to allow users of MacOS.app to access HFS and HFS+ file systems. If this group is removed or renamed, MacOS.app will not be able to access some local filesystems, and will refuse to run unless you are logged in as root.

Apple file services uses group permissions to control remote access to exported filesystems. If you set the group of an exported filesystem to anything other than "macos", then non-root users will not be able to access these filesystems in MacOS.app. To set the group for exported file systems using Remote Administration, click Disk & Share Points and click the disk or folder you want to share, then click Set Privileges.

Symbolic Links in Shared Mode

The R1.1 version of Mac OS X Server supports UNIX symbolic links in the Workspace. However, MacOS.app does not understand symbolic links on volumes mounted in shared mode. When a symbolic link is seen by the Finder or any other application in MacOS.app, the underlying file system always resolves the link. This would be like always resolving a MacOS alias. This behavior is not normal in a MacOS environment, so you may run into unpredictable results if you try to use symbolic links on volumes that are accessed in shared mode. One symptom you may see is a folder that does not contain any items or fewer items than there should be. If you must use symbolic links on volumes accessed by MacOS.app in shared mode, you may want to place the links in a well known directory (a folder called "symlinks", for example). Alternatively, name the symbolic link so it appears at the end of directory when sorted by name (zMyLink, for example). This problem will be fixed in a future version of Mac OS X Server.

Sound Input /Output

When MacOS.app starts up, it uses Mac OS X Server's sound preferences to initially set volume, balance, and mute levels. Changes to these preferences in MacOS.app will also change Mac OS X Server's preferences. While MacOS.app is running, changes to Mac OS X Server sound preferences will not change MacOS.app sound preferences.

Playing sound from an application running in Mac OS X Server at the same time an application is playing sound in MacOS.app may result in unpredictable results.

Sound input is not currently supported. This will affect speech recognition software.

Video Capture

Video capture is not currently supported.

Special Hardware Support

Some applications that require special hardware support, such as the Apple Video Player, will not work correctly under the BlueBox. These applications fail during startup and incorrectly post dialogs suggesting they could work if extensions are added to the System Folder.

Using Localized Disk Images

When starting up on the localized disk images available with MacOS.app, the default keyboard setting while running in Mac OS may differ from the keyboard setting in the Workspace. In Mac OS, this can be changed using the Keyboard control panel. Refer to the "Using different languages" section of Mac OS Help - available from the Help menu in the Finder.

Copy and Paste Between Mac OS and Mac OS X Server

Applications are advised to always use the Scrap Manager to access the Scrap. Direct scrap access may not behave correctly.

When copying data from MacOS.app to a Mac OS X Server application, it may take a noticeable period (up to several seconds) before the pasteboard is synchronized with data from the MacOS.app clipboard. If a paste is performed before this time (e.g., immediately after switching out of MacOS.app), the data may be incorrect, and the paste should be performed again.

System Folder Pieces

Just as with any Mac OS system, when applications are installed, they sometimes install resources into the System Folder on the startup volume. If you later change the startup volume or System Folders, those applications which require resources located in the System Folder, may not work as desired. In order for these applications to run correctly, you must either run the installer or manually move the appropriate pieces to the startup volume System Folder.

Serial

Serial is not supported in this release of MacOS.app; applications attempting to open either port will receive a notInitErr (-900). A future release of MacOS.app will have serial support.

Printing

Because serial is not yet supported, attempting to print to a serial-attached printer will hang MacOS.app.

Mouse Acceleration

MacOS.app uses Mac OS X Server's cursor acceleration for its own, so use Mac OS X Server's mouse preferences to configure cursor acceleration for MacOS.app. The Mac OS Mouse control panel will have no affect on cursor acceleration.

Video

Switching between Mac OS X Server and Mac OS can only happen at SystemTask() time. If Mac OS is hung, running a game which doesn't call SystemTask() or WaitNextEvent(), or sitting in MacsBug, you can't switch. You can still use Command-Shift-Q to force MacOS.app to quit. If this does not work, then the Mac OS X Server part of MacOS.app is hung and you will have to either telnet in from another machine and kill the MacOS.app process, or do a hard reboot of Mac OS X Server.

Similarly, if you switch to Mac OS X Server and then Mac OS hangs, you can't switch back. In that case, you must kill the MacOS.app process from Mac OS X Server. If MacOS.app drops into MacsBug while hidden, you may be able to unhide MacOS.app, but user input will not work. Command-Shift-Q should work.

The Video vertical retrace queue is hung off the System vertical retrace queue, and is therefore not synchronized with the actual monitor refresh interval.

If for any reason MacOS.app causes the Mac OS X Server cursor to go away, you can restore it with the following command from a Terminal window:

```
/System/Applications/MacOS.app/MacOS -showcursor 50
```

Multiple monitors are now supported. MacOS.app does not support display repositioning (via the Monitors control panel). If you try it anyway, you will have problems. To undo your changes, remove the "Display Preferences" file from the Preferences folder in the System Folder, and restart MacOS.app.

Some Mac OS applications that draw directly to the screen may continue to do so even after switching from Mac OS to Mac OS X Server. The occurrence of this behavior may be limited by switching to the Finder before switching to Mac OS X Server.

Video mirroring in Mac OS is the feature where both monitors of a dual-monitor system display the same exact picture. Use of this feature is not fully supported in MacOS.app. If you use video mirroring, make sure to turn it off before switching to Mac OS X Server from the application menu.

Hardware video acceleration is not yet supported.

User Input

Direct ADB access is not supported. Applications that read directly from ADB devices and expect mouse ADB events will not work.

Command-Shift-Q will force MacOS.app to quit. This only works if Mac OS is hung, not if the Mac OS X Server part of MacOS.app is hung. See more details under "Video", above.

MacOS.app will intercept the Command-Return key sequence and use it to jump to Mac OS X Server. This is the same key combination that PC compatibility cards use. However, some Mac OS applications (like MPW) need this key combination for full functionality. To disable special handling of this key combination, type "defaults write MacOS ScreenToggleKey 0" on the command line of a Terminal window.

Date & Time

To change the date, time, or time zone, use Mac OS X Server's Preferences.app, rather than the Mac OS Date & Time control panel. Changes to the date, time, or time zone using the Mac OS control panel will be ignored. Other features of this control panel, such as date and time formats and the menu bar clock, are fully supported.

Canceling the "Copying StartupDisk.img" Dialog

If the "Copying StartupDisk.img" dialog is cancelled when MacOS.app is not in the foreground (i.e., the dialog is front most, but is not active), the "Cancel" button may appear pressed, but then doesn't release. Click anywhere in the dialog to complete the cancel operation.

SCSI Based Printers

MacOS.app does not support printing to the LaserWriter SC, or any other SCSI-based printer that requires the LaserWriter SC 7.0.1 driver.

Apple Software

The Mac OS Setup Assistant will allow the user to configure a local (serial) printer. If you do this and attempt to print to this printer, Mac OS will hang (see "Printing", above).

The Mac OS Setup Assistant on MacOS.app takes a little longer to configure printers than it does on native Mac OS. During this time do not select any menu or you will hang MacOS.app.

The Graphing Calculator has a bug which can cause a crash when running its "Mouse Control" demo and the application is located high in memory. This also happens on native Mac OS, but is much more common in MacOS.app.

The AppleCD Audio Player does not work in MacOS.app without additional configuration. Since the AppleCD Audio Player uses the SCSI Manager to find CD-ROM drives, this causes the application not to work in MacOS.app because CD-ROM drives are not mounted in SCSI mode by default in MacOS.app.

If the AppleCD Audio Player does not find at least one CD-ROM drive, it will return an error indicating that the CD-ROM drive is not responding. Some CD-ROM drives can be enabled to use direct SCSI access; see the section on the "Blue Volume Mount Options" control panel for instructions on how to switch the mode. If direct SCSI access is enabled on at least one CD-ROM drive, the AppleCD Audio Player will launch with no error and audio CDs can be played from MacOS.app, although audio playthrough is not supported.

Apple Video Player refuses to launch because MacOS.app does not currently support video capture.

When using the Extensions Manager, some of the installed Apple software is not a part of the "Mac OS 8.6 all" set (for example, "AppleScript" and "QuickTime"). This is normal when newer releases are installed.

Disk Copy prior to version 6.3.3 cannot mount images on a Mac OS volume that is in the Shared Access mode.

MacOS.app does not contain all the necessary Unicode converters to handle file and folder names on HFS+ volumes that were created on a native Mac OS machine using a system script other than Mac OS Roman. For example, if you take an HFS+ volume that was used on native Mac OS with the Japanese language kit installed, and you access it on Mac OS X Server, the file and folder names will appear garbled.

Third-Party Software

MacBench 4.0 crashes since it attempts to access hardware that is not supported by MacOS.app. MacBench 3.0 works correctly and MacBench 5.0 works with the exception of the problem noted previously in the paragraph entitled MacBench 5.0.

Networking modes promiscuous/raw are not supported in MacOS.app; therefore, applications such as Etherpeek are not supported.

Versions of CodeWarrior prior to the Pro 4 release do not support debugging; everything else seems to work. CodeWarrior Pro 4 (IDE 3.1) with version 1.3.6 of the MetroNub supports debugging and break/watch points.

RAM Doubler attempts to access the internals of Mac OS Virtual Memory and is therefore not compatible with MacOS.app.

Virtual PC attempts to access the internals of Mac OS Virtual Memory and is therefore not compatible with MacOS.app.

Disk Doubler Pro (and especially its Finder Menu feature) is not compatible with Mac OS 8.5 or later, and therefore not with MacOS.app.

Speed Doubler causes MacOS.app to hang at startup, presumably because it attempts to modify undocumented Mac OS internals, and is therefore not compatible with MacOS.app.

The Disinfectant system extension (installed via the Protection menu of the Disinfectant application) should not be installed because it can cause some applications to quit with errors (such as Type 1 error). Conflict Catcher and Note Pad are particularly likely to crash when Disinfectant is present. Such errors are more likely to occur on

MacOS.app than on native Mac OS because of the memory allocation scheme used in MacOS.app. Disinfectant is no longer supported by its developer, who recommends a full-featured virus protection program.

Adobe Persuasion 4.0's installer frequently fails with a bus error because of a bad memory access. Due to memory layout, this rarely occurs on native Mac OS, so a workaround is to run the installer there. Adobe has discontinued this product.

If drives formatted with FWB's Hard Disk Toolkit are mounted in "Shared" or "Exclusive" mode, any driver-level password protection will be ignored. Data that is encrypted will be inaccessible. Mounting these drives in "Direct SCSI" mode will re-enable password protection and access to encrypted data.

Descent II, like many other video games, uses SCSI Manager calls as part of its copy protection. By default, MacOS.app accesses SCSI disks via Shared mode. In both Shared and Exclusive mode, SCSI-level access is disallowed. The CD-ROM drive needs to be manually configured for direct access via SCSI mode. This can be done with the "Blue Volume Mount Options" application. However, the "Blue Volume Mount Options" application cannot set an ATA/IDE/ATAPI CD-ROM drive to direct SCSI mode. See the section on the "Blue Volume Mount Options" control panel for more information.

Mac OS 9: "Add to Keychain" Checkbox Is Dimmed (Gray)

This article explains why you may not be able to add an AppleShare server password to your Keychain.
This article has been archived and is no longer updated by Apple.
In some instances, when connecting to an AppleShare server you may not able to add it to you keychain because the 'Add to Keychain' checkbox is dimmed (gray).

Figure 1, "Add to Keychain" checkbox is dimmed

Server administrators can configure AppleShare IP 6 not to allow a computer to automatically log on. Having your password in a keychain can be unsecure if your keychain is unlocked. Not allowing a computer to automatically log on can improve security.

System 7.5.5: Clean Installation Procedure

This article contains the procedure for performing a clean installation of System 7.5.5.
This article has been archived and is no longer updated by Apple.

Step 1: Find out which version of system software you should install.

The earliest version of system software you should install on your Macintosh computer is System 7.5.5. Apple has tested this version for Year 2000 compliance on Macintosh computers back to and including the Macintosh Plus. It is available for free download from Apple's Web site. See step two for more information on how to get it.

System 7.5.5 requires at least 4 MB of memory and up to 21 MB of hard disk space. Make sure your computer meets these minimum requirements before proceeding.

Your Macintosh computer may be able to use a later version of system software if it came with a later version, or if you purchased an upgrade. For more information on performing a clean installation of versions later than 7.5.5, please see the links at the end of this article.

Step 2: Get the system software you need.

Find the system software CD or floppy disk set that came with your computer. If it includes System 7.5.3, you only need to get System 7.5.5 Update.

Download

System 7.5.5 can be downloaded from the Apple Software Downloads Web site (http://www.apple.com/swupdates/) in a two-step process. First, you must download System 7.5.3, then System 7.5.5 Update.

Step 3: Start up the computer from the Disk Tools disk, or system software CD.

If your computer only has a floppy drive, start up the computer using a Disk Tools disk. If your computer has a CD-ROM drive, start up the computer using your system software CD.

Step 4: Run the Disk First Aid program to repair any errors.

After you have started up the computer from the Disk Tools disk or the system software CD, open the Disk First Aid program. Select the hard disk you want to check by clicking on its icon in the Disk First Aid window. Click the Verify button. Disk First Aid checks your disk for any errors. If Disk First Aid reports any errors, click the Repair button to repair them. Quit the Disk First Aid application.

Step 5: Update the hard drive driver software.

Find the appropriate hard drive utility for your computer on the Disk Tools disk or system software disc. Use Apple HD SC Setup with Macintosh computers that have a Motorola 680x0 family microprocessor and a SCSI hard drive. The following Macintosh computers have IDE hard drives and require that you use the Drive Setup application:

- Macintosh LC 580
- Macintosh LC 630
- Macintosh LC 630 DOS
- Macintosh Quadra 630 series
- Macintosh Performa 580 series
- Macintosh Performa 630 and 640 series
- PowerBook 190 series

Apple HD SC Setup

Open the Apple HD SC Setup application. Click the Drive button until the name of your hard disk you want to update appears. Click the Update button, then the Quit button.

Drive Setup

Open the Drive Setup application. Click the name of the hard disk you want to update. Choose Update Driver from the Functions menu. Quit the

application.

Step 6: Open the System 7.5.3 Installer application.

If you downloaded System 7.5.3 to your computer's hard disk, find and open the file called System 7.5.3 01of19.smi, then open the Installer application.

Step 7: Choose the Clean Installation option.

When the Installer application has opened, click Continue. Make sure Easy Install is selected from the pop-up menu. Press the Command, Shift and K keys on the keyboard. Select Install New System Folder and click OK.

Step 8: Click Clean Install to begin installation.

Click Clean Install to being the installation. When it has finished, restart the computer. Find and open the Installer application for System 7.5.5 Update. Click Install.

You have now finished installing a clean version of System 7.5.5 on your computer. The contents of your old System Folder are in a new folder named Previous System Folder.

You may need to install additional software such as fonts, printer or other device drivers, and application support files. You should reinstall these items from their original disks.

Macintosh Portable: RAM Consumes Insignificant Power

Is there a significant decrease in battery life for a Macintosh Portable with 2MB of Apple Portable RAM as compared to one with 1MB? Also, does the extra 1MB of Apple Portable RAM drain the battery during "Shut Down?"

This article has been archived and is no longer updated by Apple.
When the Macintosh Portable is in a "Sleep" or "Shut Down" state, having 1MB of RAM draws 4.5mA, and adding another 1MB in the RAM expansion-card slot raises the total draw to 6mA. Though we haven't tested the longevity of the battery with the additional 1MB of RAM, it should have a very minimal effect.

When the Macintosh Portable is active, the RAM power requirements are approximately 20 to 35mA with 1MB or 2MB of RAM installed, respectively. This power draw is relatively insignificant, a mere increase of 15mA, as compared to the 200mA the logic board draws, 50 to 70mA for the display, and 700mA for the hard drive.

Of course, this applies to Apple's Portable RAM expansion, because third-party RAM boards may use different kinds of RAM with different power consumption characteristics.

QuickTime 4.1.2: What‘s New

This article describes the new features in QuickTime 4.1.2.
This article has been archived and is no longer updated by Apple.

Streaming Works Better Through More Firewalls and Proxies
QuickTime streaming works better through more firewalls and proxies.

Improved MP3 Features in QuickTime Plug-in
Added MIME types to work with MP3 playlists (.m3u files).

Works With Windows 2000
QuickTime works with Windows 2000.

Improved QDesign Streaming
QuickTime includes significant improvements in the transmission of live and stored streams when using the QDesign codec. These improvements are compatible with earlier versions of QuickTime.

Improved Compatibility With Kodak Picture CDs
You can open picture files on a Kodak Picture CD using the QuickTime Plug-in.

New SMIL File Extension
Replaced .smi extension with .sml for SMIL support.

Broadband Network Improvements
Fixed situations that caused high packet loss on some networks (including @Home).

Mac OS 9: About Adobe Software Read Me

The contents of this article are from a Read Me file included with Mac OS 9.
This article has been archived and is no longer updated by Apple.

About Adobe Software

This document describes the Adobe software included in this folder.

Acrobat Reader
Adobe Acrobat Reader allows viewing and printing of any Portable Document Format (PDF) file. There may be several PDF files on the computer's hard disk and on the system software CD that came with the computer. Use Adobe Acrobat Reader to view or print these files.

Adobe Type Manager
Adobe Type Manager (ATM) installs a control panel which allows you to use PostScript fonts. Adobe Type Manager installs into the active (boot) System Folder, even if another hard drive was selected.

Important: To use the "Acrobat Reader" or "Adobe Type Manager" installers from Adobe, do not use the Mac OS CD as the startup disk. If the Mac OS CD is the startup disk, an error will occur when the Adobe installer attempts to write files to the CD. The Mac OS CD should be used as the startup disk only for installation of System Software.

Mac OS 9: About the 5XXX/6XXX Tester Read Me

The contents of this article are from a Read Me file included with Mac OS 9.
This article has been archived and is no longer updated by Apple.

About the 5XXX/6XXX Tester

This document describes the 5XXX/6XXX Tester application. This application checks Power Macintosh and Performa 5200, 5300, 6200, and 6300 series computers for hardware problems that may cause the computer to freeze. The tester only works on Power Macintosh and Performa 5200, 5300, 6200, and 6300 series computers.

Important: The Power Macintosh or Performa 6360 does not have this hardware problem. If you have a Power Macintosh or Performa 6360, you do not need to use the tester program.

If you are experiencing problems with your computer other than system freezing, you should contact an Apple-authorized service provider to obtain a full diagnostic test.

How to use the tester application

To use the tester application, double-click its icon.

After the tester has checked your computer, you'll see a message. If the message indicates that a problem has been found, contact an Apple-authorized service provider or Apple customer support to have your computer repaired. The necessary repairs are covered under a repair extension program.

Macintosh Portable: SCSI Termination Problems (1/95)

I have a Macintosh Portable to which I have connected separately either an Apple Tape Backup or external hard drive. In either case, the presence of the SCSI device crashes the SCSI system even though it is terminated correctly.

Could it be that the Macintosh Portable and other new Apple systems do not generate the initial termination due to a change in the CMOS chip?

This article has been archived and is no longer updated by Apple.
There are no known problems using Apple's external SCSI hard drives or the Apple Tape Backup on the Macintosh Portable. However, because the Macintosh Portable doesn't provide termination power (to limit demands on the battery), external SCSI devices connected to the Macintosh Portable must provide that power. That is, they must be powered on and left on while using the Macintosh Portable. Also, the Macintosh Portable should be shut down when connecting or disconnecting peripherals.

We don't know your Macintosh Portable configuration, the software used, the software versions, the events leading up to the error, or what the error was, but what is described above about termination power is common enough that it bears repeating.

If by "initial" termination you mean that the Macintosh Portable does not have "built-in" termination, it is just like all other Macintosh systems except for the Macintosh IIfx. They are internally terminated.

Final Cut Pro 1.2.1: Incorrect Recapture of PAL Clips

There is an issue with the way that Final Cut Pro 1.2.1 recaptures clips that are in PAL format. This article describes the incorrect behavior, as well as a workaround to avoid it.

Note: This issue has been resolved in Final Cut Pro 1.2.5. The Final Cut Pro 1.2.5 Update can be downloaded from the following Web site: http://www.apple.com/finalcutpro/ .

This article has been archived and is no longer updated by Apple.

Symptom

Users of Final Cut Pro and PAL devices may see an incorrect behavior when performing the following steps:

- Capturing PAL video clips
- Editing the clips into a sequence
- Discarding the original material and recapturing it

During recapture, Final Cut Pro attempts to capture all the clips that are used in sequences with more media than was originally captured, resulting in unexpected differences in the sequences in which they are used.

Solution

When capturing in PAL, always keep a separate log of clips in the browser. When you need to recapture the clips, follow these steps:

1. Keeping your current project open, create a new project.
2. Copy all the clips from the original project browser to the new project browser.
3. Close the original project so that your new project has no sequences inside of it.
4. If the copied clips have user defined In and Out points, clear them now. The In and Out columns in the browser can be cleared in their entirety by using the Clear contextual menu command in the desired column. (Press the Control key and click to see the menu.) See Figure 1.

Note: If you leave these columns set with user in and out points, the batch capture tool will not recapture the entire original clip.

Figure 1: The Clear Contextual Menu Command in the Browser

5. Recapture the clips in your new project.
6. When this is done, relink the files in your original project to the files you just captured. (For instructions on how to relink files, see page 269 of the Final Cut Pro manual.)

Note: This issue has been resolved in Final Cut Pro 1.2.5. The Final Cup Pro 1.2.5 Update can be downloaded from the following Web site: http://www.apple.com/finalcutpro/ .

iMovie: Unable to Export Movies Using Sony DVMC-DA2

Make sure the LANC cable is connected to your video camera when you export a movie using a Sony DVMC-DA2.
This article has been archived and is no longer updated by Apple.

Symptom

When you try to export a movie, an alert box appears with this message:

> "There is not a tape in the camera, please make sure that you have a tape inserted and that it is not write protected."

Solution

If you are using a LANC/Control-L device:

- Make sure the LANC cable is connected to your video camera or VCR. (See your user's manual for more information.)

If you are not using a LANC/Control-L device::

1. Set iMovie preferences to "play through to camera."
2. Set the Sony converter to DV in.
3. Click the play button in the iMovie window.

These settings will output video through the Sony DVMC-DA2 for recording to a VCR or other analog devices.

Final Cut Pro: Stops Responding When Certain Effects Are Used

Final Cut Pro stops responding, or "freezes," when the Dither Dissolve transition or the Noise generator are used.
This article has been archived and is no longer updated by Apple.

Symptom

Final Cut Pro stops responding, or "freezes," when the Dither Dissolve transition or the Noise generator are used.

Solution

- Do not use the Dither Dissolve transition or the Noise generator effects.
- Use a different model Macintosh computer to apply these effects in your project.

Published Date: Feb 18, 2012

iMovie 2: System Requirements

This article outlines the system requirements for iMovie 2.
This article has been archived and is no longer updated by Apple.
iMovie 2 requires the following:

- A Macintosh computer with a 300 MHz or faster PowerPC G3 or G4 processor and built-in FireWire port
- At least 64 MB of RAM (128 MB recommended)
- A CD-ROM or DVD-ROM drive
- 200 MB of available (unused) hard disk space (4 GB recommended; 5 minutes of imported digital video requires about 1 GB of disk space)
- A monitor that works with 800 x 600 pixel resolution and thousands of colors (1024 x 768 pixel resolution and millions of colors recommended)
- Mac OS 9.0.4 or later
- QuickTime 4.1.2 or later
- FireWire 2.4 or later (FireWire Support and Enabler extensions)
- A digital video (DV) device, such as a camcorder or deck, with a FireWire, IEEE 1394, or i.LINK port
- A 4-pin-to-6-pin FireWire cable (for use with DV camcorders)
- Viewing Desktop Movies on a TV or VCR from your DV device requires appropriate connection cables

A list of compatible cameras and DV devices is available in document number 113546 "**iMovie 2: Compatibility**."

Macintosh: System Error Codes Explained

This article explains what some Macintosh system errors actually mean. You can use them to interpret what is happening when your Macintosh gives these errors.

This article has been archived and is no longer updated by Apple.
Because Mac OS is a sophisticated, complex operating system, the difficulties you encounter can be equally complex.

These are examples of some difficulties that may occur:

- A handle can be de-referenced.
- A routine can get a NIL pointer.
- The stack can dip into the heap for just a few cycles and not be caught by the stack sniffer.
- An application can forget to check an error code.

A Macintosh usually stops responding ("crashes") with a system error code while running under System 6.0.x. Starting with System 7, errors are displayed in a different fashion. Instead of displaying an error code, the system translates the code to the appropriate words, like "Address Error".

Finding out what's wrong involves use of debugging tools, intricate knowledge of Macintosh memory structures, and familiarity with the application itself. Fixing it usually involves recompiling the source code. The table below explains some of the codes.

ID=01 Bus Error
This means the computer tried to access memory that doesn't exist. You can get this error on almost any Macintosh. If one of these computers tried to access one or more bytes beyond the total number of bytes in RAM, you see a bus error. You should never see this error on a Macintosh Plus or SE, because address references that are out of bounds "roll over". This means if one of these computers tries to access one byte beyond the total bytes in RAM, it actually accesses the first byte in memory. If you see this error on a Macintosh Plus or SE, it's reporting the wrong error or experiencing hardware failure.

ID=02 Address Error
The Motorola 68000 microprocessor can access memory in increments of one byte (8 bits), one word (16 bits), or one long word (32 bits). The microprocessor can access a byte of information at an odd or even memory address. But it must access a word or long word at an even memory address. So, when the microprocessor attempts to read or write a word or long word at an odd address, you see this error. Since that's a 50/50 proposition when running random code, this one shows up quite often.

ID=03 Illegal Instruction
The computer has a specific vocabulary of machine language instructions it can understand. If a computer tries to execute an instruction that isn't in its vocabulary, you see this error code. It's less likely than error 02, but still very common.

ID=04 Zero Divide Error
This error results if the microprocessor divides two numbers, and the divisor is zero. Sometimes a programmer puts these in as debugging aids, and then forgets to take them out.

ID=05 Range Check Error
Programmers can use an instruction in the Motorola 68000 to check if a number is within a certain range. This error indicates that the number tested isn't in the specified range.

ID=06 Overflow Error
Each number stored in a computer is given a certain amount of space. The larger the number, the more space is needed to represent the number. An overflow condition results if a generated number is too big for its allotted space. A Motorola 68000 instruction tests for an overflow condition, and displays this error if it detects an overflow.

ID=07 Privilege Violation
The Motorola 68000 runs in Supervisor or User mode. The Macintosh should always be in Supervisor mode, but sometimes is placed in User mode. Some of the instructions can only be executed in Supervisor mode. If the computer attempts one of these instructions while in User mode, a Privilege Violation error results.

ID=08 Trace Mode Error
A programmer can use a runtime debugger while in Trace mode. This allows tracing through a program one instruction at a time. You see this error if a debugger isn't installed and the 68000 is accidentally placed in Trace mode.

ID=09 and ID=10 Line 1010 & 1111 Trap
There are many routines in the Macintosh ROM that can be called by placing instructions in a program that aren't in the 68000's vocabulary. When the 68000 encounters such an instruction, it looks it up in the instruction table. This table gives the location of routines paired with each instruction. If it finds an entry in the table for the instruction, it branches to the routine. If there's no entry for the instruction, you see one of these errors.

ID=12 Unimplemented Core Routine
A programmer might set breakpoints in parts of a program to inspect for errors. This requires using a debugger. If a debugger isn't installed when a breakpoint occurs, you see this error code.

ID=13 Uninstalled Interrupt
The Macintosh uses an interrupt to identify when devices like keyboards and disk drives need service. Routines must be available in memory to tell the computer how to service the device. If those routines aren't available, you see this error.

ID=15 Segment Loader Error
Macintosh programs are broken up into segments, and each program always has at least one segment. Multiple segments allow loading parts of the program into memory to provide more room for data in internal RAM. The segment loader is responsible for loading a needed segment into RAM. If the segment loader can't do this, this error appears.

ID=17 through ID=24 Missing Packages 0-7
The Macintosh uses packages to do specific tasks. Some of the packages are International Utilities, Binary-Decimal Conversion, Standard File Utilities, and Disk Initialization. These packages are located in the System file. If you get these errors, you probably have a damaged System file. Error codes 15, 16, 26, 27, 30, and 31 also come up when the System file is damaged. Try replacing the System file.

ID=25 Memory Full Error
You've probably run out of RAM. But you can get this error when an earlier error causes the Macintosh to falsely detect an out-of-memory condition.

ID=26 Bad Program Launch
The Macintosh couldn't execute the application opened.

ID=28 Stack Ran into Heap
This is similar to the Memory Full error. It's a good idea to save your work frequently, and keep current backups of your hard disk data. When a system crash does occur, you'll lose less data if you've taken these precautions.

Other error codes can be found in the following Tech Info Library articles:

Article 9804: "**Mac OS System Error Codes: -299 to -5553**"
Article 9805: "**Mac OS System Error Codes: 0 to -261**"
Article 9806: "**Mac OS System Error Codes: 1 to 32767**"
Article 9808: "**Mac OS System Error Codes: Uncommon Codes**"
Article 16456: "**Apple Remote Access: Error Codes**"
Article 18173: "**MacTCP: Error Codes Defined**"
Article 18566: "**PowerTalk and PowerShare: Error Code Listing**"
Article 19791: "**Open Transport: Error Codes**"

Troubleshooting System Errors

It's a good idea to save your work frequently, and keep current backup copies of your hard disk data. When a system crash occurs, you'll lose less data if you've taken these precautions.

If you're getting system errors frequently, investigate these possibilities:

- Try to open the document with a current version copy of the application.
- Try opening other documents with the same copy of the application.
- Check to see if the document size exceeds the application size limits.
- Start up your system with extensions off (restart while holding the Shift key down).
- Any changes (new Control Panels, extensions, etc.) you've made to the system might give you a clue to the cause of the errors.
- Make a note of the desk accessories you had open at the time of the error and exactly what you did before the error.
- Make a note of the error ID or text, and the version numbers of the application and system software you were using.
- Try to recreate the behavior on another Macintosh.
- Perform a clean installation of your system software and try the application again.

Macintosh Manager: "No Printer Has Been Selected" Alert Message

This article discusses an issue where Macintosh Manager client computers display an alert box with the alert message: "No printer has been selected in the Chooser."
This article has been archived and is no longer updated by Apple.

Symptom

Client computers display an alert box with the following alert message when users try to print:

> "No printer has been selected in the Chooser."

You may also see Desktop Printer icons that are crossed out when opening System Access.

Solution

These symptoms likely indicate that the Printing Preferences file is unusable. Follow these steps to rebuild it:

1. Log into System Access.
2. Drag the Printing Preferences folder to the Trash.
3. Drag all Desktop Printers to the Trash.
   Note: Desktop Printers may also be in the Users folder (on the root of the startup volume) or the Secured Items folder (in the System Folder).
4. Disable the Multi-User Startup extension.
5. Restart the client computer.
6. Open the Chooser.
7. Select a printer.
8. Enable the Multi-User Startup extension.
9. Restart the client computer.

Final Cut Pro 1.2.5: Captured Video Files Limited to 2 TB

Final Cut Pro 1.2.5 can capture digital video files up to 2 terrabytes (TB) in size.
This article has been archived and is no longer updated by Apple.
Using Mac OS 9, QuickTime 4.1.2 or later, and Final Cut Pro 1.2.5, you can capture DV clips up to 2 TB in size. The disk you capture to must be a Mac OS Extended format disk.

If necessary, you can limit the size of captured DV files to 2 GB in Final Cut Pro's Scratch Disk preferences tab.

Note: File sizes may be limited to 2 GB if you capture clips using a video capture card. Check with the card's manufacturer for more information.

QuickTime 5 Public Preview: Final Cut Pro Compatibility Information

This article provides information on the compatibility of Final Cut Pro and QuickTime 5 Public Preview.
This article has been archived and is no longer updated by Apple.
On 2000-10-10 Apple released the public preview of QuickTime 5. The purpose of this preview release is to allow developers and users to test and provide feedback on the next generation of digital media technology.

While every effort has been taken to assure the reliability of the QuickTime 5 Preview, it is important to understand that it is trial, prerelease, time-limited software meant for evaluation and development purposes only. The Preview release should not be used in a commercial operating environment or with important data. Before installing QuickTime 5 Preview, you should back up all of your data and regularly make backups while using the software.

Of the many enhancements in QuickTime 5, one of the best for Final Cut Pro users is a new DV CODEC. This new CODEC provides enhanced render performance and a number of quality improvements. However, there are several known issues that affect Final Cut Pro when working with the new DV CODEC included with the QuickTime 5 Public Preview.

- Playing back long DV clips on computers with dual microprocessors and Mac OS ROM version 5.5.1 causes the computer to stop responding, or "freeze." This issue does not occur on computers with a single microprocessor, or dual-processor computers with ROM versions prior to 5.5.1.
- Video playback in the Log & Capture window on computers with dual microprocessors and Mac OS ROM version 5.5.1 causes the computer to stop responding, or "freeze."
- The FireWire output of certain types of images, for example a composite of a 2-color gradient, displays and records incorrectly (it will have jaggies) on Panasonic, Canon, and possibly other DV camcorders.

Note: You may use one of these methods to identify your computer's Mac OS ROM version:

Option 1 (preferred)
Use Apple System Profiler. The ROM file version is listed under "Production Information".

Option 2
From the Finder, Choose About This Computer from the Apple menu. If the computer has ROM version 5.5.1 it will be displayed. Not all ROM versions prior to 5.5.1 are displayed in this dialog.

QuickTime: Windows troubleshooting tips

Learn troubleshooting tips for QuickTime software on Windows-based computers.
This article has been archived and is no longer updated by Apple.
Although the following tips are related to Microsoft Windows and PC hardware/software configuration, these steps may help to resolve issues.

Troubleshooting Tips

- Make sure your computer meets the system requirements.
- Try running ScanDisk to verify that the directory is OK. This is an important step to take before installing any software.
- Try running the stand-alone version of the QuickTime installer in "Safe Mode." It is available here. This can help to isolate issues with background applications, and some driver conflicts.
- Make certain you have installed the most recent drivers for your sound and video cards. Even if you have a "brand new" computer, it is not guaranteed to have the most recent software installed. Contact the manufacturer of your sound and video cards for additional information.
- Make certain you have installed a recent version of DirectX.

Errors are usually related to software conflicts, unusable files, or incompatibilities. They can also be related to specific hardware combinations, and sometimes the way in which the hardware is configured. Keep in mind that an error message does not necessarily point to a particular cause or solution. Since there can be many different causes for a particular symptom, some suggestions may not work, and you may need to discover a solution on your own.

Note: Please contact Microsoft Corporation or your computer vendor for help configuring Microsoft Windows.

Macintosh: How to View GDDM Files on Host

I want to view GDDM files using a terminal application (with board or preferrably Ethernet-supported) for 3192G or 3279G terminal types. Can you help?

This article has been archived and is no longer updated by Apple.
The latest release of DCA's (formerly Avatar) MacMainFrame product supports both features you want. It provides APA (All Points Addressable) graphics, and it distributes sessions across AppleTalk to other Macintosh systems on the network. Because the product emulates a 3279 terminal with APA graphics, you can use GDDM on the host to display graphics on the Macintosh.

Because you mentioned Ethernet as a preferred connection, we assume you're looking for a TN3270 solution. We haven't used it personally, but we understand that the latest TN3270 product from Brown University Computing and Information Services supports several IBM graphic terminals (3179G, with GDDM support).

Also, you might want to contact Wollongong with regard to their MacPathway TN3270 product. To locate a vendor's address and phone numbers, use vendor name as a search string.

Article Change History:
26 July 1993 - Company title changed from Avatar to DCA (Digital Communication Associates)

iTunes 1.0: System Requirements

This article outlines the system requirements for iTunes 1.0
This article has been archived and is no longer updated by Apple.
To use iTunes 1.0 music software, your computer must meet the following system requirements:

Listen to music

- iMac or later computer
- Mac OS 9.0.4, Mac OS 9.1 recommended
- Internet connection for CD database

Make an audio CD

- Power Mac G4 computer with internal Apple CD recording drive
- Use CD-R media with a 74-minute capacity for music.
  CDR media is available directly from the online **Apple Store**.

Notes

1. All of iTunes features may not work if you install the North American English version on a computer that has a different language version of the Mac OS.
2. Versions of iTunes for International English, Japanese, French, German, Italian, Spanish and Dutch are available. Brazilian Portuguese, French Canadian, Norwegian, Danish, Finnish, Chinese, Swedish and Korean versions are expected to be made available soon.

iTunes: Only One Application Can Use Disc Drive at a Time

Only one application can use a computer's disc (CD or DVD) drive at a time.
This article has been archived and is no longer updated by Apple.

Symptom

You can play an audio CD with the iTunes application, but when you open the AppleCD Audio Player application, iTunes stops playing the CD.

Solution

Quit the AppleCD Audio Player application. Only one program can control the disc drive at a time. iTunes and AppleCD Audio Player cannot both be used to play an audio CD at the same time.

Published Date: Feb 18, 2012

iTunes: Compatible Audio File Types

iTunes can import and play many different kinds of audio files.
This article has been archived and is no longer updated by Apple.
iTunes 1.0 and later can import and play the following audio file types:

- AIFF
- AIFC
- audio CD
- MP3
- System 7 Sound (SND)
- uLaw (AU)
- WAV
- QDesign
- QuickTime audio (audio only movies)

iTunes 3 and later can also play these additional file types:

- Audible.com (format 2, 3, and 4)

iTunes 4 and later can also play these additional file types:

- AAC (Advanced Audio Coding)
- MP4

To add these kinds of files to your iTunes library or playlists:

1. Click the Library icon in the iTunes window.
2. Drag the file's icon into the iTunes window.

You can also add these sounds to your library by choosing Add To Library from the File menu. If you choose a folder or disk, all the audio files it contains will be converted using your current import preference settings. To change the settings:

1. Choose Edit > Preferences (choose iTunes > Preferences in Mac OS X)
2. Click the Advanced tab (click the Importing tab in Mac OS X).
3. Choose a default encoder from the Import Using pop-up menu.

iTunes 1.0: Rio 600, 800, and Nike PSA[play Appear in Source List When Turned Off

Certain hardware MP3 players appear in iTunes' Source list even when they're turned off.
This article has been archived and is no longer updated by Apple.

Symptom

You drag a song from a playlist or the library to the icon of an MP3 player in the Source list, and an alert box with the following error message appears:

> "Attempting to write to media module 'internal Flash memory' failed with error 9001. The media may be defective."

Solution

The hardware MP3 player is probably turned off, but still appears in the Source list.

1. Disconnect the hardware MP3 player from the computer.
2. Turn the player on.
3. Reconnect it to your Macintosh computer.
4. Copy the song(s) to your player.

iTunes 1.0: Turn on Nomad II Docking Station Before Opening iTunes archive

Your computer appears to stop responding or "freeze" after you put your Nomad II MP3 player in its docking station.
This article has been archived and is no longer updated by Apple.

Symptom

Your computer appears to stop responding or "freeze" after you put your Nomad II MP3 player in its docking station. An alert box appears with an error message that says the device is not turned on, and the display on the Nomad II player says, "Please power the docking station."

Solution

Make sure the Nomad II docking station is plugged in and turned on. Your computer should start working when you turn on the docking station.

iTunes: Full Screen Visuals Don‘t Display on a TV

If you connect your PowerBook computer to a television, iTunes' Full Screen visuals may not work. Follow the steps in this article to watch iTunes' Full Screen visuals on your TV.
This article has been archived and is no longer updated by Apple.

Symptom

You connect your PowerBook computer to a television to watch iTunes' Full Screen visuals, but the screen remains in Small, Medium, or Large. It won't switch to Full Screen. You may also see a blank, black screen on the TV and the PowerBook display.

Solution

1. If video mirroring is on, turn it off in the Control Strip. iTunes' Full Screen Visuals do not work with TV mirroring.
2. Put the PowerBook in sleep mode by closing the display.
3. Disconnect the TV from the PowerBook.
4. Wake the PowerBook by opening the display.
5. In the Control Strip or Monitors control panel, set the PowerBook screen resolution to 640- by 480-pixels.
6. Put the PowerBook in sleep mode by closing the display.
7. Connect the TV.
8. Wake the PowerBook by opening the display.
9. Play a song in iTunes with Full Screen Visuals.

Notes

1. You can display Full Screen Visuals on a PowerBook computer's display without following these steps.
2. If you disconnect your computer from the television, change resolutions, or restart the computer, you will need to follow these steps again to watch iTunes' Full Screen Visuals on your television.

Apple DVD Player: Black Bars at Top and Bottom of Screen

When watching a movie from a DVD-Video disc there are black bars at the top and bottom of the screen even though Fill Screen or Present Video on Screen is selected in the Video menu.
This article has been archived and is no longer updated by Apple.

Symptom

When watching a movie from a DVD-Video disc there are black bars at the top and bottom of the screen even though Fill Screen or Present Video on Screen is selected in the Video menu.

Solution

This is normal due to differences in the monitor's aspect ratio, and the movie's aspect ratio. You do not need to change or correct anything.

For more information on why DVD-Video discs behave this way, see article 60795 "**Apple DVD Player: Why Black Bars Surround the Picture**."

iTunes: Long Gaps Between Songs

You may need to reduce the amount of time iTunes inserts between songs if you make a custom audio CD from your audio CD collection.
This article has been archived and is no longer updated by Apple.

Symptom

There are long gaps between songs on custom audio CDs that you burn with iTunes.

Solution

Some or all of the songs you used to burn the audio CD already have gaps, and iTunes is inserting additional time between songs. You should reduce the amount of time iTunes inserts between songs.

1. Choose Preferences from the Edit menu.
2. Click the Advanced tab.
3. Choose a shorter length of time, perhaps None, from the Gap Between Tracks pop-up menu.
4. Insert a blank CD-R disc.
5. Click Burn CD.

QuickTime 5 Public Preview: Sound Manager or QuickTime Alerts at System Startup Time

You should install a later version of QuickTime 5 if the Public Preview version installed on your computer expires.
This article has been archived and is no longer updated by Apple.

Symptom

When you start up your computer an alert box with one of these error messages appears:

> "The Sound Manager extension has expired."
>
> "QuickTime MPEG Extension has expired. See 'http://www.apple.com/quicktime' for a newer version.'
>
> "QuickTime installation failed because this beta version has expired. See 'http://www.apple.com/quicktime' for a newer version."

Solution

The version of QuickTime 5 Public Preview installed on your computer has expired. Download and install the latest version of QuickTime 5 from http://www.apple.com/quicktime/ .

If you continue to see these alert boxes after installing the latest version of QuickTime 5, follow the instructions in article 31309: "**QuickTime: How to Remove QuickTime 5 Public Preview**" and then reinstall the latest version of QuickTime 5.

Published Date: Feb 18, 2012

iTunes: Cannot Install From Software Install Disc

You cannot install iTunes from the Software Install disc if it is also the startup disk.
This article has been archived and is no longer updated by Apple.

Symptom

When you try to install iTunes from the Software Install disc, an alert box appears with a message that says the disk is locked and the installation cannot take place.

Solution

The iTunes installer cannot install software on your computer's hard disk if the Software Install disc was used to start up the computer. Restart the computer using the hard disk as the startup disk, or follow these steps:

1. Copy the iTunes installer folder from the Software Install disc to the computer's hard disk.
2. Open the iTunes installer.
3. Install iTunes onto the hard disk.
4. After the computer has restarted, drag the iTunes installer to the Trash.

iTunes 1.1/Disc Burner 1.0.1: Third-Party Disc Burning Software Stops Working

Third-party disc burning software may stop working after you install iTunes 1.1, or Disc Burner 1.0.1.
This article has been archived and is no longer updated by Apple.

Symptom

Third-party disc burning software stops working after you install iTunes 1.1 or Disc Burner 1.0.1

Solution

1. Use the Extensions manager control panel to create an extensions set for your third-party disc burning software.
2. Turn off these system extensions:
   - USB Authoring Support
   - FireWire Authoring Support
3. Turn on the system extensions used by your third-party disc burning software.
4. Restart the computer.

When you want to use iTunes or Disc Burner to burn a disc, open the Extensions Manager control panel and switch back to original extensions set. You may also consider turning off the third-party disc burning software system extensions in this set. Although Authoring Support and iTunes Extension override most third-party system extensions, it may be helpful to turn off the third-party extensions regardless.

For information on creating an extensions set with the Extensions Manager control panel, read article 30929: "**Mac OS: Extension Conflict Troubleshooting/Extensions Manager Features**."
Published Date: Feb 18, 2012

iTunes 1.1: Compatible Third-Party CD-RW Drive Mechanisms

This article explains how to find out if your third-party CD-RW drive is compatible with iTunes 1.1.
This article has been archived and is no longer updated by Apple.
This following list of compatible drives is included with the iTunes 1.1 Read Me file.

These CD drive mechanisms are supported:

- LG (CD-RW CED-8042B)
- Matshita (CD-RW CW-7121, CD-RW CW-7586, UJDA310)
- Mitsumi (CR-4802TE, CR-4804TE)
- Philips Iomega (CDD4801 CD-R/RW, ZIPCD 650)
- Pioneer (DVD-RW DVR-103)
- Plextor (CD-R PXW1210A, CD-R PX-W8432T, CD-R PX-W8220T, CD-R PX-W124TS)
- Ricoh (CD-R/RW RW8040A)
- Samsung QPS (CD-R/RW SW-208B)
- Sanyo LaCie (CDBP-121032, CDBP-161040, CRD-BP1300P)
- Sony (CD-RW CRX140E, CD-RW CRX700E, CD-RW CRX140, CD-RW CRX145, CD-RW CRX160, CD-RW CRX700, CD-RW CRX10U)
- Teac (CD-W24E)
- Yamaha (CRW4416, CRW6416, CRW8424, CRW8824, CRW2100)

If your drive is not recognized, you may not have a compatible drive or some other CD driver software is preventing its use. If you have installed other software that burns CDs, use Extensions Manager to turn off its extensions. See article 60805: "**iTunes 1.1: Third-Party Disc Burning Software Stops Working**" for more information about using third-party disc burning software.

Published Date: Feb 18, 2012

iTunes: Compatible Personal MP3 Player Isn‘t Recognized

Your personal MP3 Player may not be recognized by iTunes if you install an earlier driver than the one that comes with iTunes.
This article has been archived and is no longer updated by Apple.

Symptom

iTunes does not recognize a compatible MP3 player device, even though you've installed the USB drivers that came with the player.

Solution

Reinstall iTunes. The USB drivers that came with your player are too old. The iTunes installer will install later USB drivers that are compatible.

Published Date: Feb 18, 2012

iTunes 1.1: Remove CD Master Files

iTunes 1.1 cannot write to a compatible third-party CD-RW drive if you have installed other incompatible disc burning software.
This article has been archived and is no longer updated by Apple.

Symptom

You are unable to burn an audio CD even though the drive mechanism is compatible with iTunes.

Solution

Remove the CD Master plugins from the Authoring Support Files folder in the Extensions folder.

Note: CD Master authoring files were not part of iTunes 1.0.x and are not compatible with iTunes 1.1.

For a list of compatible CD-RW drive mechanisms, see article 60806: "**iTunes 1.1: Compatible Third-Party CD-RW Drive Mechanisms**."
Published Date: Feb 18, 2012

Fiber Optic Network Developers

Do you happen to know of sites in the U.S. or Europe where fiber optics are being tested or used as the transport media in a LAN of Macintoshes and possibly PCs?

This article has been archived and is no longer updated by Apple.

Although we don't know of any devices that bring fiber optics into the Macintosh (for example, a fiber optics NuBus card), there are numerous companies that offer Ethernet-, Token Ring-, and LocalTalk-to-Fiber Optics transceivers. So a network could look like:

```
Macintosh<-->LocalTalk<-->transceiver<-->fiber<-->transceiver<-->
EtherTalk<-->Macintosh
```

Just a few of the companies offering such products are Berg Electronics (formerly DuPont Electronics), Network Resources Corporation, and SynOptics. Other similar devices are readily available from network-product suppliers like Black Box Corp. Routing AppleTalk over that medium is not a problem. Additional information on these companies can be found in the Technical Info Library.

A significant number of corporations, universities, and government agencies are using (or experimenting with and preparing to use) fiber to some degree. For information on established networks with particular characteristics, contact the vendors of the products you are considering.

Article Change History:
27 July 1993 - Company title changed from DuPont Electronics to Berg Electronics.

Published Date: Feb 18, 2012

iTunes 1.1: Custom Installation Does Not Install Extensions for Third-Party Drives

Installing the custom installation of iTunes 1.1 does not install system extensions for third-party drives.
This article has been archived and is no longer updated by Apple.

Symptom

The About iTunes 1.1 document says:

> **"Important:** With FireWire and USB CD-RW drives, you may not be able to use third-party CD burning software after you install iTunes. Contact the manufacturer of the CD burning software for updates that resolve this issue. To avoid this issue, when you install iTunes choose the option that does not install the CD authoring support."

However, the first custom installation option says: "iTunes Application with CD Authoring Support". See Figure 1.

Figure 1 iTunes custom installation option

Solution

You can use the first custom installation option. It installs the software necessary to burn a disc using an Apple CD-RW drive, but it does not install software for third-party USB and FireWire drives. Use the Easy installation or the second custom installation option to install software for third-party drives.

Final Cut Pro: May Stop Responding When Connecting Offline Media Clip

If you open a media clip that is already in use in Final Cut Pro with another application, either application may stop responding or "freeze" when you reconnect the clip in Final Cut Pro.

This article has been archived and is no longer updated by Apple.

Symptom

Final Cut Pro stops responding or "freezes" when you reconnect a media clip that was opened with another program.

Solution

Close the media clip in the other program before reconnecting it in Final Cut Pro.

Published Date: Feb 18, 2012

Final Cut Pro: Lengthy Delay in Writing 20-bit Audio with Targa Ciné System

If you use 20-bit audio in a sequence, you can experience a lengthy delay when editing to tape.
This article has been archived and is no longer updated by Apple.

Symptom

If you have 20-bit audio in your sequence and you edit to tape, Final Cut Pro displays a dialog that says "Writing audio...". It can take 30 minutes or more to finish writing the audio depending on how much 20-bit material is in the sequence.

Solution

Only use 8- or 16-bit audio in your sequence. The delay happens because QuickTime is converting the audio in 16-bit space.
Published Date: Feb 18, 2012

Final Cut Pro 2: Rerenders High Definition 23.976 Files Exported From After Effects

Final Cut Pro 2 may appear to needlessly rerender High Definition 23.976 frame rate files exported from Adobe After Effects when you import them into a 23.98 time base sequence

This article has been archived and is no longer updated by Apple.

Symptom

Final Cut Pro 2 rerenders High Definition 23.976 frame rate files exported from Adobe After Effects when you import them into a 23.98 time base sequence.

Solution

Final Cut Pro 2 does not work with frame rates of 23.976/23.98.

Published Date: Feb 18, 2012

Final Cut Pro 2.0: Cleaner 5 System Extensions Conflict

System extensions installed with Terran's Cleaner 5 application may interfere with video capture, playback, and YUV processing in Final Cut Pro. This article has been archived and is no longer updated by Apple.

Symptom

These symptoms may occur in Final Cut Pro 2.0 after you install Cleaner 5:

- Slow, choppy capture
- Fields seem to be reversed in capture and playback
- Unexpected frame dropping
- Unwanted brightness shifting

Solution

Use the Extensions Manager control panel to turn off these extensions when you use Final Cut Pro:

- RadDVCodec
- RadDVDecoder

You can turn them back on when you use Cleaner 5.

Final Cut Pro 2: "Error Importing EDL" Message With Sony 9100 Format EDLs

You should use Sony 3600 Format EDLs when you export from AVID Media Composer to Final Cut Pro 2.
This article has been archived and is no longer updated by Apple.

Symptom

When you import Sony 9100 Format EDLs that were exported from AVID Media Composer, an alert box with this message may appear:

"Error importing EDL."

Solution

Use the Sony 3600 Format to export EDLs from AVID Media Composer.
Published Date: Feb 18, 2012

iTunes 2: How to Use the Same Library in Mac OS 9 and Mac OS X

This document explains how to set up iTunes 2 in Mac OS 9 and Mac OS X to use the same music library.
This article has been archived and is no longer updated by Apple.
You can share your music library between the Mac OS 9 and Mac OS X versions of iTunes 2 by making an alias of the iTunes folder, inside your Documents folder. The iTunes folder contains the iTunes Music Library file and the iTunes Music folder with your encoded songs. **Important:** These steps do not work with iTunes 3. You cannot share music libraries between Mac OS 9 and Mac OS X if you use iTunes 3.

To use the Mac OS 9 music library with Mac OS X:

1. Drag the iTunes folder that may already exist in the Documents folder of your Mac OS X home to the Trash.
2. Make an alias of the iTunes folder that is inside your Documents folder on your Mac OS 9 startup disk.
3. Drag the alias to the Documents folder that is inside your Mac OS X home.
4. Rename the alias from "iTunes alias" to "iTunes".

Now, when you use iTunes for Mac OS X, it will follow the alias and use your music library from Mac OS 9.

To use the Mac OS X music library with Mac OS 9:

1. Drag the iTunes folder that may already exist in your Documents folder on the Mac OS 9 startup disk to the Trash.
2. Make an alias of the iTunes folder that is inside the Documents folder in your Mac OS X home.
3. Drag the alias to the Documents folder that is on your Mac OS 9 startup disk.
4. Rename the alias from "iTunes alias" to "iTunes".

Now, when you use iTunes for Mac OS 9, it will follow the alias and use your music library from Mac OS X.

AlisaShare: User Limit "around" 62

I have the following configuration:

- DEC VAX 6000 series running VMS 5.3 PCSA and AlisaShare

- All-Ethernet environment

The VAX is dedicated to desktop services, including file and print sharing. When more than 62 users log on to the VAX using AlisaShare, the process locks up and must be restarted. Even when this limit is approached and users log off, the process remains locked. The VAX is currently serving over 200 Macintosh and MS-DOS systems.

I spoke with Alisa Tech Support and was told the limit for AppleShare in general was 62 users and could not go beyond that. They suggested starting a second Alisa Process to cover additional needs, but I am reluctant to do this because of the extra time needed to administer it.

I know of the 50-user limit of Apple's AppleShare server software and the 254-node limitation of AppleTalk Phase 1, but not of a maximum limit of 62 simultaneous users.

Do you know of any such limitation? If yes, is there a workaround? If not, what could be the source of the problem?

This article has been archived and is no longer updated by Apple.

We contacted Alisa Technical Support and they told us that AlisaShare has a user limit of "around" 62 users. This is not an AppleShare limit. Starting another process is the only way we know to work around this problem.

Data Access Language (DAL): Distributed Sessions

I am very interested in the Data Access Language, especially in relation to a DB2 database. Does DAL support accessing the IBM mainframe via distributed-session, 3270-connectivity products like Avatar's distributed session product or Tri-Data Netway?
This article has been archived and is no longer updated by Apple.
Data Access Language (DAL, formerly CL/1) uses a connection definition in the hosts.cl1 file when making connection to a DAL host server. The following mainframe interfaces are currently supported by DAL:

- MacDFT 1.1 with Apple Coax/Twinax Card connection
- MacDFT 1.1 with Apple TokenTalk NB card connection
- MacDFT 1.1 with Apple Serial NuBus Card Connection
- Tri-Data Netway 1000/2000 connection
- Avatar MacMainFrame connection
- DCA MacIrma connection

CVT and DFT sessions are supported byt all these connection methods.

iTunes for Mac OS X: Set Sleep to Never When Burning Audio CDs

Your computer may stop responding and iTunes will fail to successfully burn an audio CD if the computer or display goes to sleep.
This article has been archived and is no longer updated by Apple.

Symptom

The computer stops responding, or "freezes," and iTunes fails to create a usable audio CD.

Solution

Update to iTunes 4.0.1 or later. The current version of iTunes can be downloaded from the iTunes download page (http://www.apple.com/itunes/download/).

iTunes: USB CD-R Drives Should Be Set to 2x Burn Speed

You should set your USB CD-R drive to 2x burn speed when you make an audio CD with iTunes.
This article has been archived and is no longer updated by Apple.

Symptom

iTunes does not successfully burn an audio CD on a USB CD-R drive if the burn speed is set higher than 2x.

Solution

You should set your USB CD-R drive to 2x burn speed when you make an audio CD. iTunes may not be able to successfully burn an audio CD at speeds higher than 2x on some USB drives. To set your drive to 2x speed, follow these steps:

1. Choose Preferences from the iTunes menu (Mac OS X) or Edit menu (Mac OS 9).
2. Click the Advanced tab or the CD Burning tab (depending on your version of iTunes).
3. Choose 2x from the Burn Speed pop-up menu.
4. Click OK.

iTunes 1.1.1 for Mac OS X: Click Burn Before Inserting Blank Discs

You should open the iTunes application and click Burn before inserting a blank disc.
This article has been archived and is no longer updated by Apple.

Symptom

When you insert a blank CD, an alert box appears with a message that asks if you to continue, eject, or initialize the volume (disc).

Solution

1. Click Continue.
2. Click Burn in iTunes to create the CD.

To avoid this message, click Burn before inserting a blank disc. If you can't eject a blank CD after you've inserted it, try clicking the eject button in iTunes.

DVD Studio Pro 1.0.1: Clipped Frames When Encoding With MPEG 2 Into PAL

This article describes an issue that you may experience when encoding with MPEG 2 into PAL.
This article has been archived and is no longer updated by Apple.

Symptom

When you encode with MPEG 2 into PAL and then open the clip in DVD Studio Pro, the last few seconds are clipped.

This does not happen if you encode into NTSC.

Solution

This issue is addressed in DVD Studio Pro 1.1. To get more information about DVD Studio Pro and to download the latest update, visit the DVD Studio Pro product page at:

http://www.apple.com/dvdstudiopro/

A/UX: How It Handles Multiple Monitors and Function Keys (9/94)

I have some problems with A/UX:

1) Since A/UX supports only one monitor, which monitor will A/UX use on a Macintosh SE/30 with an external monitor (RasterOps)?

2) The command shell in A/UX uses a VT100 definition in the termcap file. How are the VT100 keys mapped to the Apple extended keyboard (like the VT100 keypad, PF1-PF4)?

This article has been archived and is no longer updated by Apple.
A/UX uses only the internal monitor when running on a Macintosh SE/30. A/UX running on a Macintosh II class machine will always use the video card installed in the lowest number slot.

The PF1 through PF4 function keys on the extended keyboard are supported under the A/UX 3.0 CommandShell terminal emulation. Use the "Keys" pull down menu.

A/UX 2.0: How to Protect the Macintosh OS Partition

I want to put in a lab of A/UX systems to teach UNIX on. In A/UX 2.0b9 I found a hole for lab use. That is, you can boot A/UX; log in as guest, root, or regular account; and throw away the System folder from the Macintosh OS boot partition. If the system is then powered down, it can't be restarted. This is a serious problem for public-access types of facilities. Is this also in the final?

This article has been archived and is no longer updated by Apple.
This problem remains in the released version, but here's a temporary solution:

1) Format the A/UX drive using Silverlining from La Cie.

2) Password protect the Macintosh OS partition using Silverlining.

3) Put only a System file and the A/UX Startup application on the Macintosh OS side. NO Finder should be put on the Macintosh OS side.

4) Set A/UX Startup as the startup application after you have started up from a floppy or another disk.

A/UX 2.0 will not recognize the password-protected disk and will not mount it. Because the Macintosh OS side has only a System file and the A/UX Startup application, no one can short-circuit the boot into A/UX and mess with the Macintosh OS files.

However, two possibilities remain for tampering with the Macintosh OS side. Making a bootable floppy that has a Finder on it from A/UX could be troublesome. A clever hacker could use "dp" to remove the password protection on the Macintosh OS side. However, proper file protections could stop this sort of thing. You might also have to protect power switches.

In A/UX 3.0, A/UX Startup includes a password feature that can make the MacPartition unavailable to all users except root.

Mac OS X 10.0: Cannot Assign a Name to LPR Printers

Mac OS X 10.0 through 10.0.3 do not offer a feature to name an LPR printer.
This article has been archived and is no longer updated by Apple.

Symptom

You are unable to change a printer's IP address to a name.

Solution

These versions of Mac OS X 10.0 do not include a feature to change the IP address to a name in the Print Center.

Mac OS X Server 10.0: Mail Server Email Addresses Can Use Long Name

Mac OS X Server's Mail Server will work with email addresses using the user's long or short name.
This article has been archived and is no longer updated by Apple.
When setting up the Mail Server, you can use a user's long name, and are not limited to the eight-character short name.
A user's long name is limited to 63 characters.

If you plan to use the long name you should only use alphanumeric characters, underscores, and dashes, which are 'safe' characters. You should avoid spaces, punctuation marks, and other 'special' characters.

Technically, the email RFCs permit spaces and many other 'special' characters, but typical conventions avoid them, so you should avoid them for best compatibility with other email clients and servers.

TA44514_AFE_Incompatibility_with_AUX__(TIL06087).pdf

AFE: Incompatibility with A/UX 2.0

Article Change History

08/31/92 - REVIEWED
*For technical accuracy

AFE (under A/UX 2.0) fails to initialize DSDD disks as MS-DOS 720K, with the error "Initialization Failed!" The same disks formatted fine on an MS-DOS machine, another Macintosh running AFE, and the same A/UX Macintosh booted under Macintosh OS. The results were the same on several different disks regardless of whether DOS Mounter was running or not.

This article has been archived and is no longer updated by Apple.
AFE isn't completely compatible with A/UX 2.0, although formatting 720K DOS disk was the only problem I found with it. It would mount and translate both 720K and 1.44MB DOS disks with no problems.

Sherlock: "Another process changed the volume during the search" Alert

If you change the contents of a disk or volume that Sherlock is searching, Sherlock stops searching and an alert box appears.
This article has been archived and is no longer updated by Apple.

Symptom

Sherlock stops searching and an alert box with this message appears:

> "Unable to search the volume '<VolumeName>'. Another process changed the volume during the search. Please wait for the process to finish and try again."

Figure 1 Sherlock alert box

Solution

This alert appears if you change the contents of a disk or volume while Sherlock is searching. You change the contents of a disk or volume by saving or copying a file to it, or by dragging an item to the Trash or to another disk or volume. To prevent this alert box from appearing, avoid changing the contents of a disk or volume while Sherlock is searching.

WebObjects 4.5: End of Support Notice

This article contains an important WebObjects announcement.
This article has been archived and is no longer updated by Apple.
In 2001-05, Apple released both WebObjects 5 and WebObjects 4.5.1. WebObjects 5 represents the future of WebObjects, allowing users to deploy all-Java solutions built using WebObjects' award-winning technology. WebObjects 5 is available worldwide through The Apple Store, Apple retail stores, and selected resellers.

WebObjects 4.5.1 is a transitional product designed for the use of existing WebObjects 4.5 customers. This release allows deployment of Objective-C based WebObjects applications on Mac OS X 10.0, and includes a number of improvements for all platforms. All customers currently using WebObjects 4.5 should upgrade to this new release. WebObjects 4.5.1 is only available by telephone order from The Apple Store.

An upgrade offer is available for WebObjects 4.5 customers to upgrade to WebObjects 4.5.1. This offer expires on 2001-09-14. Please visit http://www.apple.com/webobjects/ or your regional WebObjects page for more details.

Effective 2001-07-02, Apple will no longer make WebObjects 4.5 licenses available. However, the license keys included with WebObjects 4.5.1 may still be used with WebObjects 4.5 deployments, allowing you additional time to transition.

Apple typically supports the current release of WebObjects, as well as the latest update to the previous release. In accordance with this practice, on 2001-11-01, Apple will no longer make WebObjects 4.5 technical support available. Apple continues to provide regular fee-based support and updates for WebObjects 4.5.1 and we expect to do so for some time to come.

Additionally, effective 2001-12-31, Apple will discontinue the availability of WebObjects 4.0.1 licenses and technical support. Please plan accordingly.

Apple will of course continue to fulfill its obligations under existing contracts to license and support software products that may be subject to this notice.

Questions or comments may be sent to webobjects@apple.com.

Desktop Skills Tutorial: Sounds Are Distorted When QuickTime 5.0.1 Is Installed

When QuickTime 5.0.1 is installed, the sounds associated with the Desktop Skills tutorial are distorted.
This article has been archived and is no longer updated by Apple.

Symptom

Sounds generated by the Desktop Skills tutorial are distorted.

Solution

Download and install QuickTime 5.0.2. There are two ways to do it:

- Open the QuickTime Player application.
- Choose Update Existing Software from the Help menu.

-Or-

- Download the QuickTime 5.0.2 installer from the QuickTime Web page (http://www.apple.com/quicktime/download/).

Additional information

Canon Elura (NTSC)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon GL1 (NTSC)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon Mini DV MV3i (PAL)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Using Assemble Edit, the sequence consistently appears 5 frames before the set In Point. When using the tuner scripts, the sequence will appear 3 frames before the set In Point.

Canon MV20i (PAL)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified..

Canon MV200i (PAL)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon MV30i (PAL)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon Optura Pi (NTSC)
Timecode refresh of DV tapes not recorded on the Optura Pi will stutter in Final Cut Pro 1.2.5 and on the Optura Pi LCD screen. This may result in dropped frame warnings, or timecode break detection warnings after capturing clips. Use only tapes that were recorded on the Optura Pi for editing.

This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon Ultura (NTSC)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon XM-1 (PAL)
This camera needs the DV Tuner 2 and CMP Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 2" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Canon ZR10
Using Assemble Edit to print Final Cut Pro 1.2.5 projects to tapes that have been continually used and worn may contain audio drops. If you experience this problem, use a new tape.

Panasonic PV-DV100
This camera also needs the DV Tuner 1 and CMP Override Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These are included with Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 1" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Panasonic PV-DV200, PV-DV400, PV-DV600, and PV-DV800
These devices and the Panasonic PV-DV100 have similar FireWire hardware so they should be compatible with Final Cut Pro 1.2.5. These devices were not tested but are being considered compatible based on the test results of the PV-DV100.

These cameras also require the DV Tuner 1 and CMP Override Scripts to optimize device control over FireWire with Final Cut Pro 1.2.5. These files are included with the Final Cut Pro 1.2.5 installer and updater. Once installed, locate the folder called "Extras" and you will find "DV Tuner 1" and "CMP Override". Drag these two files into the Final Cut Pro Plugins folder before launching Final Cut Pro. These Scripts should NOT be installed when using other DV devices, unless specified.

Sony DCR-TRV7
When batch capturing clips widely separated by timecode, you may receive an incorrect error message stating that Final Cut Pro was "...unable to find timecode..." Individually capture clips separated by 3 minutes or more when using this camera.

Sony DSR-11
If the deck is switched from NTSC to PAL (or vice versa) while importing into Final Cut Pro, you must restart the computer to reset the FireWire bus for the signal change to be recognized.

Sony DVMC-DA1
The Sony DVMC-DA1 is no longer available from Sony but is supported for Final Cut Pro 1.2.5.

Sony DVMC-DA2
If your device is only equipped with the LANC device control connection, LANC will not transmit timecode to Final Cut Pro. However, you may use the media converter functions to convert video for transmit over FireWire. Device control will be available when using LANC however, timecode will be omitted preventing usage of such functions as, Batch Capture, and Capture Clip. These functions require a timecode reference to operate.

Aurora Video Systems Igniter
You must use version 1.2 of the Igniter driver with Final Cut Pro. Onscreen VGA video playback may suffer slightly in certain situations, especially with high data rates. Setting your display color depth to thousands instead of millions, setting the Igniter playback preview size to quarter, or setting Playback Preview mode to Computer Only will all help increase the onscreen playback performance. Additionally, the Igniter card supports –10dBu audio. If you are using +4dBu audio, you must use a mixer or an inline pad to adjust the incoming audio levels. The Analog Upgrade card for the Igniter supports +4dBu audio. The Igniter uses a compression ratio of 1.5:1 at its best setting. Data rates can vary due to the nature of the material being captured..

Digital Voodoo D1 Desktop 64 AV
Version 4.8.1 of the D1 Desktop driver has been qualified. The D1 Desktop Firmware revision 26 has been qualified. 10 Bit data rates are about 26.7 Megabytes/second and require a robust disk drive subsystem. Due to high data rates, 10 Bit sequences with upwards of 8 tracks of audio may require a mix-down of audio tracks for final playback.

DC30Plus
Video play back on the Mac monitor is not a true representation of the video quality. In order to see the actual video quality, video must be played out to

a television or NTSC monitor.

Make sure you are using a video card capable of overlay (for example, ATI RagePro.) Set your Monitor to Thousands of Colors and Final Cut Pro View size windows to 50 percent, this will improve playback on the VGA monitor. Try reducing the Overlay size using the DC30plus control panel, set to very small or small if overlay is not updating the window correctly.

Optimal performance with Final Cut Pro is video frame size at 640 by 480 NTSC. Earlier versions of DC30plus capture cards are not able to handle +4dBu from Professional sources. A mixer may be used to adjust the levels between the source and DC30plus card.

NewerTechnolgy – FireWire 2 Go
If you are using Final Cut Pro on a PowerBook G3, turn off all "Energy Saver" settings while using FireWire Out/In for DV capture and playback in Final Cut Pro.

Panasonic AJ-D250
The AJ-D250 requires a software upgrade to support the optional FireWire (IEEE 1394) interface. All VTRs shipped after 2000-09 include this software upgrade. If you have an older deck, Panasonic will update the software for a flat fee of 150 USD at an authorized service center. Please contact Panasonic for additional details.

Pinnacle Systems TARGA Ciné engine
To better handle the high data rate requirements of uncompressed video, set the size of the Final Cut Pro Canvas and Viewer windows to less than 95 percent on slower computers.

Pinnacle Systems TARGA 2000 SDX Studio
TARGA 2000 SDX Real-Time and Accelerated effects are not enabled in Final Cut Pro. This capture card requires TARGA 3.1.1 drivers to perform correctly.

Pinnacle Systems TARGA 2000 DTX
This card requires TARGA 3.1.1 drivers to perform correctly.

RATOC Systems CBFW2 FireWire CardBus
Turn off all "Energy Saver" settings while using FireWire Out/In for DV capture and playback in Final Cut Pro. We recommended not using the PowerBook Sleep function while using Final Cut Pro. CBFW2 card is to be used with the PowerBook G3.

Sony DSR-40
All Edit to Tape functions must be used with Apple FireWire device control protocol.

When using Black and Code, the deck will cue to PAUSE mode. You must hit stop manually on the deck to start Black and Code. Black and Code will start automatically.

Log & Capture Mode Issue with the PowerBook (FireWire) computer.
The following Final Cut Pro qualified DV devices require Mac OS 9.0.4 in order for Log & Capture mode to work correctly:

Sony DSR-20
Sony GV-D300
Sony GV-D900
Sony PC-10
Sony TRV-7
Sony TRV-9
Sony TRV-9E
Sony WV-D9000

Mac OS 9: Cannot Install Because System is "Too Large"

During an upgrade installation of Mac OS 9, an alert box appears with a message that says installation cannot continue because the System file is "too large".
This article has been archived and is no longer updated by Apple.

Symptom

While performing a Mac OS installation over an existing System Folder, an alert box appears with this message:

> "The file 'System' on the disk is too large to accommodate the installation. Try removing 'System' and install again."

Products Affected

- Mac OS 9.0 through 9.2.1

Solution

1. Open the System Folder.
2. Open the file named System.
3. Remove any non-Apple resources you may have added such as alert sounds or keyboard layouts. These resources can be reinstalled after you have updated the operating system.
4. Try performing the Mac OS 9 installation again.

Mac OS 9.2: iTunes and Volume Control Using the Apple Pro Keyboard Volume Keys

This article explains how the Apple Pro Keyboard volume keys work in conjunction with iTunes and system volume with Mac OS 9.2 and later
This article has been archived and is no longer updated by Apple.

Symptom

The system volume does not change when using the Apple Pro Keyboard volume keys, only iTunes volume changes.

Solution

This is normal. When iTunes is open, iTunes controls the volume keys. You can change the volume in iTunes, but not the system volume.

Quitting iTunes allows the system volume to be changed using the keyboard volume keys.

LaserWriter: Remote Status Feedback (11/94)

I am using the LaserWriter IINTX in PostScript batch mode, attached to a Hewlett-Packard workstation. The printer's location makes it impossible to see the status lights. Can one write a program to read the status and notify the user of a condition requiring operator intervention?

What is the difference between "PostScript batch" and "PostScript interactive" modes? Would "PostScript interactive" give me the capabilities I need? Are these modes described anywhere?

This article has been archived and is no longer updated by Apple.
PostScript batch mode is the mode to use. To quote page 275 of the PostScript Language Reference Manual (available from Addison-Wesley):

"In batch mode, a job consists of the execution of a single file containing a PostScript program."

The manual goes on to say:

"In interactive mode, a job consists of an arbitrarily long dialogue in which the user issues a PostScript statement and the server executes the statement and prompts for the next one."

Page 282 of the manual discusses status queries:

"The LaserWriter provides a status query facility that enables the host or user to determine what the LaserWriter is doing. The LaserWriter responds to a status query asynchronously with respect to normal job execution; that is, it sends a response immediately, regardless of what has gone on before or how much input data has been buffered. This facility is intended primarily to enable 'spoolers' (printer control programs) to keep track of the activities of LaserWriters under their control."

"The status query mechanism works differently depending on whether AppleTalk or serial communications is in use, but the syntax and semantics of the response are the same in either case."

"In case of AppleTalk, a request to open a connection to a busy LaserWriter yields a rejection packet whose data consists of a status message. There is also a separate status request packet that yields the same information. The path over which the status response packet travels is logically separate from the connection through which the server is receiving its current job."

"In case of serial communication, receipt of a control-T character from either channel (9-pin or 25-pin connector) elicits a one-line status message over the same channel. This channel need not be the one through which the server is receiving its current job. The message is bracketed by the text sequences '%%[' and ']%%' to enable host software to extract the message from ordinary data generated by the job being executed."

Mac OS 9.1, 9.2.1: No Scroll Bars in Finder Windows

If you connect to a file server using the Launcher, the scroll bars in Finder windows disappear.
This article has been archived and is no longer updated by Apple.

Symptom

After you connect to a file server by clicking its icon in the Launcher, Finder windows no longer have any scroll bars.

Solution

Use any of these workarounds:

- Click the Launcher window, then click a Finder window. The scroll bars reappear.
- Connect to server volumes using the Chooser or an alias on the desktop instead of the Launcher.
- Continue to use the Launcher to connect to server volumes, but add the server and your name and password to the keychain in the log-on dialog. Be sure to give Finder access to the keychain by checking the box "Allow 'Finder' to access keychain without warning."

DVD Player 3.0: Subtitles Disappear After Using Forward or Backward Controls

When playing a movie from a DVD-Video disc using DVD Player 3.0 (included with Mac OS X 10.1), subtitles can disappear after clicking the Forward or Backward controls.
This article has been archived and is no longer updated by Apple.

Symptom

If you have turned on subtitles while playing a movie from a DVD-video disc and then click the Forward or Backward control, when you resume play by pressing the space bar the subtitles are turned off.

Solution

Turn off the subtitles and then turn them on again.

1. Click the right side or bottom of the Controller to show the additional controls.
2. Click the Subtitle button to cycle through the available language choices. The choices appear briefly in the Viewer window.

You may also be able to choose subtitles using the disc's interactive menus.

Note: Not all DVD-Video discs have subtitles or work with this feature.

Macintosh Plus: Serial Driver Differences Of The 128K ROM

This article describes issues with RAM and ROM based serial drivers when the Macintosh Plus was introduced.
This article has been archived and is no longer updated by Apple.
When connected to third party printers, the newer ROM-based Macintosh Plus serial driver occasionally doesn't work, possibly because of differences between the old RAM and ROM drivers and the newer ROM driver.

If you have recently upgraded your system to a Macintosh Plus and your printer no longer works with some of your applications, you may have to change from Xon/Xoff (Software) to DTR (hardware) type handshaking, if your printer has this option.

There were originally three different serial drivers, two RAM serial drivers and a ROM serial driver. The RAM drivers had features that the ROM driver didn't. One version of the RAM driver was for use with the 128K and 512K Macintosh and one version was for use with the Macintosh XL. All serial drivers default to 9600 baud, 8 bits data, no parity, and two stop bits with the ROM serial driver supporting CTS hardware handshake and the RAM driver supporting Xon/Xoff software handshake. The ROM driver would terminate input requests when an error occurred. The RAM driver would not terminate with errors. It can be seen that, depending on which driver was used by an application, a user could access certain built-in functions.

The newer serial driver in the Macintosh Plus 128K ROM has some differences from all the previous drivers. The new driver verifies that the serial port is correctly configured and free; if not, an error is returned. When opened, the new driver defaults to hardware handshake ON (as did the old ROM driver). When opened, the new driver also asserts the DTR line and negates that line when closed. There have been new control calls implemented that let the application control the input data flow from an external device, as well as set control options, and modify the translation of parity default characters.

Further information on the old RAM and ROM serial drivers can be obtained from Inside Macintosh Vol. II, Page 245-255. Further information on the newer ROM serial driver can be obtained from Inside Macintosh Vol. IV, Page 225-228.

HomePage: Site Names That Begin With a Period Can‘t Be Seen in an iDisk

If you create a site in HomePage that starts with a period, the corresponding iDisk folder is not visible in the Finder.
This article has been archived and is no longer updated by Apple.

Symptom

If you create in HomePage that starts with a period, the corresponding iDisk folder is not visible in the Finder.

Solution

Remove the period as the leading character of the site name in the HomePage Manager. This will allow the folder to be seen in the iDisk.
Published Date: Feb 18, 2012

.Mac: HomePage Page Numbering System Changed

In .Mac HomePage 3.0 pages are incremented by order created.
This article has been archived and is no longer updated by Apple.
With previous HomePage-created sites, the HTML name of the page only included a number if it was the second or greater page of that category. For example, the first photo album created was titled PhotoAlbum.html, the second photo album was PhotoAlbum1.html, the next photo album was PhotoAlbum2.html, and so forth.

Since HomePage 3.0, the pages no longer number this way. Instead of counting how many pages of any one template have been created, the numbers now reflect how many pages in total have been created. Thus, if your first page is a photo album, it will be PhotoAlbum1.html. If your next page is an iMovie page, it will be iMovieTheater2.html, even though there was no iMovieTheater1.html.

A/UX 2.0: Slot Manager and Device Drivers (6/93)

I want to use a NuBus accelerator card (MacDSP) with A/UX 2.0. I got it to work under the Macintosh OS. However, when I try to get it to work under A/UX, the software says that it cannot find the device driver for the DSP NuBus card. What needs to be done to get A/UX to recognize this? Do I need to write a custom device driver for A/UX? Why does Apple map serial applications like MacTerminal correctly through the /dev/tty driver and not map SCSI devices and/or NuBus boards (Slot Manager)?

This article has been archived and is no longer updated by Apple.

Yes, a NuBus card used under A/UX must have a device driver written for it, or it will not be recognized as a valid device, and it will not function. Actually, this is similar to what we have in the Macintosh OS. For example, a .ENET driver is installed in the System file when you use the Macintosh II EtherTalk NB card, and the Apple TokenTalk NB card requires A/ROSE to function.

Therefore, although the Slot Manager provides the basic functionality of recognizing and communicating with NuBus cards at system startup, it is actually the manufacturers' software that initializes the cards and lets the system use them. This software uses the Slot Manager to integrate the cards into the Macintosh OS.

Although it provides excellent Macintosh OS compatibility, A/UX 2.0 cannot provide this low-level hardware communication in the same fashion as the Macintosh OS and remain UNIX. UNIX uses device drivers of a particular format to communicate with hardware, and just as we have had to do with the NuBus cards we support, manufacturers wishing their cards to work with A/UX must either support Apple's drivers (as in third-party video cards) or write their own.

Article Change History:
17 Jun 1993 - Retitled to show A/UX 2.0 in title.
07 Sep 1993 - Reviewed for technical accuracy.

.Mac: HomePage Created Subfolders May Not Be Modified in iDisk

When additional Web sites are created through HomePage, a subfolder is created in the Sites folder of the iDisk using the same name as the site. While the contents of this folder may be viewed, the folder itself and its contents cannot be modified. Attempting to modify the contents of this folder will result in an alert.

This article has been archived and is no longer updated by Apple.

Symptom

An alert box appears when you try to copy files to a HomePage created folder in the Sites folder of your iDisk.

Solution

It is not possible to use a HomePage created subfolder to store files or Web pages. Files may be stored at the root level of the Sites folder, or you may create your own subfolder by choosing New Folder from the File menu.

Published Date: Feb 18, 2012

Mac OS 9: "You are not permitted to change File Sharing settings" Alert

If file sharing is turned on, Limited Finder or Panels users may see a file sharing-related alert when the computer wakes from sleep, restarts, or is shut down.
This article has been archived and is no longer updated by Apple.

Symptom

If you are logged in as a Limited Finder or Panels user, when you shut down, restart, or wake the computer from sleep, an alert box with this message appears:

> "You are not permitted to change File Sharing settings."

Solution

This alert box appears because you are logged in as a user that does not have privileges to make file sharing changes. To prevent this alert box from appearing, log out before choosing Sleep, Restart, or Shut Down from the Special menu.

MacDFT, TokenTalk, and Error 32804

I am having problems with a Macintosh IIci with Apple TokenTalk NB card and MacDFT hooked to an IBM host running TSO. When I call up MacDFT 1.1, I set my terminal type to Model 3, then begin to log on. After typing my log on and password, a dialog box appears:

Session 1: Request 14: Error 32804

I can log on and run terminal sessions just fine, but this error message may appear one more time during the session. The manual gives no indication of what this problem may be.

Another, and possibly related, symptom is that file transfer, which worked fine under version 1.0, does not work; the file transfer always times out at the file transfer dialog box. Any suggestions?

This article has been archived and is no longer updated by Apple.
We suspect that both of these problems are being caused by an improperly configured Log Mode Table on the host. Specifically, we are looking at the PSERVIC field in the Log Mode Table that has the following format:

```
02 80 00000000 2050 1850 7F 00
| | | | | | |
| | reserved | | | reserved
| | | | |
| Query bit | | Screen Size Switch
| | |
LU Type | Alternate Screen Size
|
Default Screen Size
```

Where:

1) LU Type is the device type. 02 is a display device.

2) Query bit determines file transfer ability. You need the first digit of this byte set to 8 or higher to enable DFT file transfer.

3) Default Screen Size and Alternate Screen Size are values determining the terminal model being used. The following table shows the possible settings:

Model 1 1828
Model 2 1850
Model 3 2050
Model 4 2B50
Model 5 1B84

4) Screen Size Switch sets your ability to switch between the default and alternate display types. If this is set to 7F, you can. If it is set to 7E, you cannot.

In your case, we suspect that the Query bit and Default Screen Size fields need to be reset, based on the functionality you desire. It is quite likely that the settings are still those used when MacDFT 1.0 was being used through a Coax/Twinax card in CUT mode.

1. Is iPod compatible with my computer?
2. How do I tell which iPod I have?
3. What music (jukebox) software do I need on my computer to use iPod?
4. How do I transfer music between my computer and iPod?
5. I have a computer at home and one at work. Can I update my iPod music collection from more than one computer?
6. Can I update more than one iPod with my computer?
7. I have both a Mac and a PC. Will my iPod work on both?
8. Can I use my existing iPod for Mac on a PC, or my iPod for Windows on a Mac?
9. Can I use iPod while running, or doing other activities? Will my music skip?
10. How does iPod provide skip protection?
11. How much music does iPod hold?
12. What if my music collection exceeds the storage capacity of iPod?
13. Will music sound as good on my iPod as on my CD player?
14. What is the equalization (EQ) feature on iPod?
15. Can I standardize the volume for all the music tracks in my MP3 player?
16. What audio formats does iPod work with?
17. What is Audible?
18. Can I connect iPod to my home stereo?
19. Can I connect iPod to my car stereo?
20. How long does the battery last?
21. How do I charge iPod?
22. Can iPod charge while my computer is asleep?
23. How does the hard drive feature of iPod work?
24. Can I start up my computer using iPod?
25. Is there a clock on my iPod?
26. How do I add contacts and notes to my iPod?
27. How do I update my calendar on my iPod?
28. How long does my iPod service warranty last?
29. How long is iPod complimentary telephone support?
30. Where do I find help for my iPod?
31. How do I clean iPod?
32. What iPod accessories can I purchase?

Using iPod with your computer

Question: Is iPod compatible with my computer?
Answer: iPod is compatible with Macintosh computers running Mac OS X and PCs running Windows 2000 or Windows XP.
For additional information, see iPod: System Requirements.

Question: How do I tell which iPod I have?
Answer: It's easy to see which iPod model you have. Some of the things you can do include checking if it has a scroll wheel, a touch wheel, or a Click Wheel and checking the size of its hard drive. See Identifying different iPod models for more details.

Question: What music (jukebox) software do I need on my computer to use iPod?
Answer: iPod comes with iTunes for Macintosh and iTunes for Windows.

iPod is fully integrated with iTunes. iTunes allows you to "rip" tracks from CDs into MP3 or AAC format and organize your music library by creating playlists. And every time you plug iPod into your computer, your music library--complete with playlists--is automatically transferred over FireWire or USB 2.0. See the iTunes website for upgrades to iTunes.

Question: How do I transfer music between my computer and iPod?
Answer: iPod offers multiple ways to transfer music from your computer. You can set the transfer mode in iTunes 7 or later by selecting the iPod icon in the source pane to reveal the iPod settings. The following modes can be configured on the iPod:

- Automatically update all songs and playlists. This is the default mode, in which your entire music library, including playlists, is automatically synced to your iPod. If the music library on your computer exceeds the iPod storage capacity, iTunes will offer to choose a selection of songs to sync to iPod.
- Automatically update selected playlists. With this option, iTunes automatically copies only the playlists you have selected to iPod when you connect it to the computer. This option can be selected by accessing the Music tab of the iPod settings.

- Manually manage music. You can also choose to transfer music to iPod manually. This allows you to drag and drop individual songs and playlists from iTunes to iPod. You can find this option by accessing the Summmary tab of the iPod settings.

Question: I have a computer at home and one at work. Can I update my iPod music collection from more than one computer?

Answer: Yes. When you first connect iPod to your computer, iPod recognizes that computer as its "home" computer. Each time you connect, iPod automatically downloads the music library stored on it. When you connect iPod to a different computer, iTunes will inform you that iPod is linked to a different iTunes library and will ask whether you wish to erase iPod's contents and sync with the new computer's library. If you will be connecting to multiple computers frequently, configure your iPod to manually manage music. This will allow you to selectively drag songs, albums, or playlists from the second computer to your iPod without compromising the existing music.

Synchronization generally occurs only in one direction, from your computer to your iPod. This means you typically cannot transfer music, automatically or manually, from your iPod to a computer, and you cannot use iPod to copy a music library from one computer to another. An exception to this is the transfer purchases feature which allows you to restore purchased iTunes content to your computer from your iPod. Additionally, if you legally are allowed to copy music or other media files, you can configure your iPod as a storage drive to move media files.

Question: Can I update more than one iPod with my computer?
Answer: Yes. Each iPod communicates a unique device identification number to your computer, allowing you to take advantage of automatic music transfers to your iPod even if you share a computer with another iPod user. You can choose to automatically update your entire music collection on multiple iPod players or choose to update selected playlists, allowing you to transfer custom playlists to individual iPod players.

Question: I have both a Mac and a PC. Will my iPod work on both?
Answer: No, not at the same time. iPod is configured for either Mac or PC. You can use iTunes 7 or later to restore iPod to work with a Mac or a PC. See "Restoring iPod to factory settings" for more information. **Note:** Using the iPod for Mac on a PC, or using the iPod for Windows on a Mac, is not supported by Apple. FAT32 is the format used by Windows, and while some FAT32 iPod models may work with your Mac, Apple only supports using the iPod shuffle in FAT32 format on Mac. For more information see the iPod shuffle Frequently Asked Questions (FAQ).

Question: Can I use an iPod formatted for Mac on a PC, or an iPod formatted for Windows on a Mac?

Answer: It is not possible to use an iPod formatted for Mac with Windows. This is because Windows does not support the HFS Plus file system and therefore will not see the drive. When you connect an iPod formatted for Mac to your PC, iTunes will prompt you to restore the iPod.

iTunes will allow you to use an iPod formatted for Windows on a Mac; however, Apple currently only supports using the iPod shuffle in FAT32 format on Mac. For more information see the iPod shuffle Frequently Asked Questions (FAQ).

Skip Protection

Question: Can I use iPod while running, or doing other activities? Will my music skip?
Answer: iPod was designed for people with an active lifestyle. It is compact and lightweight enough to take with you wherever you go. It was designed to fit comfortably in the palm of your hand or to be slipped into a pocket or purse for easy transport. iPod offers up to 20 minutes of skip protection — twice that of other hard drive-based MP3 players on the market — so you can enjoy outdoor athletic activities without missing a beat. Also check out the skip-free iPod shuffle and iPod nano.

Question: How does iPod provide skip protection?
Answer: In addition to the hard drive, iPod has a memory cache. It is made up of solid-state memory, meaning that it has no mechanical or moving parts, so it is not affected by movement of the device. iPod skip protection works by preloading up to 25 minutes of music to the cache at a time. iPod plays music from the memory cache rather than the hard drive, so even rigorous activities won't cause music to skip.

Storage

Question: How much music does iPod hold?
Answer: iPod comes in many storage capacities from 512 MB to 80 GB.[2] The amount of music iPod can hold depends on the compression rate of your songs. At 128 kilobits per second (kbit/s), the most common compression rate used for MP3s, 20 GB is equivalent to over 5000 four-minute songs, or more than 500 CDs. At the near-CD-quality 160 kbit/s compression rate, 20 GB equals over 4000 four-minute songs, or 400 CDs.

iPod shuffle includes capacities of 512 MB and 1 GB for up to 120 or 240 AAC format songs respectively.

Question: What if my music collection exceeds the storage capacity of iPod?
Answer: If you have more music in iTunes than you can fit on iPod, you can choose to update selected playlists only or update manually. With the first option, only the tracks in the selected playlists (rather than the entire music library) are downloaded to iPod when you connect. With the manual update option, you manage what goes into your iPod by dragging and dropping selected songs or playlists into iPod.

Audio

Question: Will music sound as good on my iPod as on my CD player?

Answer: iPod is designed to provide the best-quality sound. iPod has a powerful 60 mW amplifier so it can deliver audio as loud as you want. It also has a 20 Hz to 20 kHz frequency response, which means you can hear distortion-free music at the lowest or highest pitches. Even the iPod headphones are designed to give you the best-quality sound. The earbud-style headphones rely on Neodymium transducers, a rare earth magnet that significantly enhances frequency response and overall sound quality. Most other headphones use aluminum, cobalt, or ceramic drivers; at the same size, the Neodymium driver is five times as powerful. Because the strength of the driver increases the accuracy of the sound, the iPod headphones provide a high-energy listening experience while minimizing distortion.

To ensure CD-quality sound, be sure to use a compression setting of 160 kbit/s (the default setting in iTunes) or higher when you "rip" tracks from your CD into MP3 format, or 128 kbit/s in MP4 format (AAC).

Question: What is the equalization (EQ) feature on iPod?
Answer: An equalizer allows you to adjust various audio frequencies within the sound spectrum (much like the bass and treble controls on a stereo system). Equalization can be used to optimize audio playback for a specific room, genre of music, or individual's listening preference. The iPod comes standard with over 20 equalization presets, such as Jazz, Rock, or Bass Booster. Choose your EQ preset in the Settings menu.

Question: Can I standardize the volume for all the music tracks in my MP3 player?
Answer: Music CDs are all mastered differently, with large discrepancies in volume between songs on different albums. With iPod for the Mac, you can standardize the volume of all the songs in your music library with the Sound Check feature in iTunes 3 or later. You can turn Sound Check on or off by choosing Sound Check in Settings in the main iPod menu.

Question: What audio formats does iPod work with?
Answer:

- Mac: AAC (up to 320 kbit/s), MP3 (up to 320 kbit/s), MP3 Variable Bit Rate (VBR), WAV, AIFF, Audible.
- Windows: AAC (up to 320 kbit/s), MP3 (up to 320 kbit/s), MP3 Variable Bit Rate (VBR), WAV, Audible.

For additional information see "iPod: About compatible song formats". Click here for iPod shuffle compatible formats.

Question: What is Audible?
Answer: Audible is a service that provides digital spoken versions of over 18,000 audiobooks and audio programs such as daily digests of the Wall Street Journal and The New York Times, iPod can play the Audible format. You can listen to Audible files using iTunes 4 or download them to your iPod for listening on the go.

Using iPod in Your Home and in Your Car

Question: Can I connect iPod to my home stereo?
Answer: Yes. With its powerful 60 mW amplifier and 20 Hz to 20 kHz frequency response, iPod will sound great on your home stereo. Third-party stereo adapters are available for listening to your iPod music library using home stereo speakers. Compatible devices must be self-powered and support audio output through a 3.5 mm headphone jack. For optimal sound quality when using external speakers, set the iPod volume at less than half the maximum output and adjust your listening volume through your stereo controls. This prevents overamplification, which can cause distortion and reduce audio quality.

Question: Can I connect iPod to my car stereo?
Answer: Yes. iPod will also sound great on your car stereo. Use an extension cable with 3.5 mm stereo connectors on each end to connect iPod to your car stereo system's auxiliary input, or use a cassette adapter if your car stereo doesn't have a sound input port. These items can be purchased at stores that sell car stereo accessories, or at the Apple Store.

Battery

Question: How long does the battery last?

Answer: The built-in rechargeable battery provides between 8-20 hours of music playtime[3] depending on your iPod model. See "Accurately determine your iPod battery life" for more specific information.

Question: How do I charge iPod?
Answer: There are three ways to recharge the built-in battery. First, use the 6-pin FireWire cable or high-power USB cable that came with iPod and connect it to your computer. **Note**: Only certain iPod models will charge directly over USB (iPod shuffle, iPod mini, and Fifth Generation iPod). Second, If you use the 4-pin-to-6-pin FireWire cable or if you don't have access to your computer, you can charge iPod from a standard electrical outlet an AC power adapter. Third, if you have an iPod with a dock connector and have a dock, just place iPod into its dock.

If you are a frequent traveler, you can purchase the World Travel Adapter Kit, a set of "duckheads" with prongs that fit different electrical standards, so you can charge your iPod through any electrical outlet around the world. The World Travel Adapter Kit includes six AC adapter plugs for use in North America, Japan, China, the UK, continental Europe, Korea, Australia, and Hong Kong.

Question: Can iPod charge while my computer is asleep?
Answer: Yes, in some cases. If you connect the iPod to your computer by FireWire, and your computer is sleeping and also connected to AC power, in most cases the iPod will charge. If the iPod does not charge when connected this way, either wake the computer or connect the iPod

directly to an AC power adapter.

Non-music Features

Question: How does the hard drive feature of iPod work?
Answer: iPod can double as a hard drive for your computer. This allows you to transfer files and applications from your computer to the iPod and take them with you wherever you go. iPod is smart enough to keep your data files separate from your music collection so that they will not be accidentally erased when you are updating your music.
See Using your iPod as a hard disk for more information.

Question: Can I start up my computer using iPod?
Answer: Yes, iPod can be loaded with system software and used as a startup disk for your Mac or to install system software on your Mac. Using iPod to start up your Mac with system software is an unsupported feature. iPod cannot be used to start up a PC.

Question: Is there a clock on my iPod?
Answer: Yes, iPod has a digital clock so you can keep track of the time wherever you go — especially convenient for working out.

Question: How do I add contacts and notes to my iPod?

Answer:

iTunes can automatically transfer contacts stored in Address Book to your iPod. To enable syncing of Address Book contacts:

1. Open iTunes and connect your iPod to your computer.
2. Select the iPod icon in the Source pane of iTunes.
3. Click the Contacts tab.
4. Select the "Sync Address Book contacts" checkbox.

iPod is also compatible with popular applications such as Microsoft Entourage, Microsoft Outlook, and Palm Desktop.[4] Simply export your contacts as vCards into your iPod, and you can access names, phone numbers, and addresses on the go. For instructions on creating notes click here.

Question: How do I update my calendar on my iPod?

Answer: iTunes can automatically transfer calendar data stored in iCal to your iPod. To enable syncing of your iCal calendars:

1. Open iTunes and connect your iPod to your computer.
2. Select the iPod icon in the source pane of iTunes.
3. Click the Contacts tab.
4. Enable the "Sync iCal calendars" checkbox.

iPod also supports industry-standard iCalendar and vCalendar files, which can be exported by many applications including Microsoft Entourage, Microsoft Outlook, and Palm Desktop. iCal also works with the iPod calendar. Simply drag your iCalendar or vCalendar files to your iPod, and you can access your calendar even when you are away from your computer.

Service and Support

Question: How long does my iPod service warranty last?
Answer: iPod comes with a one-year limited hardware warranty. An AppleCare Protection Plan (APP) for iPod is available. For more information, see the APP for iPod website.

Question: How long is iPod complimentary telephone support?
Answer: Newer iPods come with complimentary telephone support within the first 90 days. The complimentary support offering applies to:

- iPod classic
- iPod nano
- iPod shuffle
- iPod touch

Question: Where do I find help for my iPod?
Answer: iPod comes with extensive AppleCare built-in service and support, including onscreen help in iTunes, online support via the Apple Support Discussions Forum and Knowledge Base, and 90 days of complimentary phone support.

Question: How do I clean iPod?
Answer: Click here for information on how to clean iPod.

Accessories

TA44535_iPod_Frequently_Asked_Questions.pdf

Question: What iPod accessories can I purchase?
Answer: A range of Apple and third-party accessories is available to enhance your iPod. For prices and availability, visit the Apple Store.

- Carrying case with belt clip
- iPod remote and earphones
- Extra AC adapter
- Extra USB or FireWire cables
- World Travel Adapter Kit
- Car tape deck adapter
- Car power adapter
- Splitter cable

Notes

iPod and iTunes are for legal or rightholder-authorized copying only. Don't steal music.

1. Capacity based on average song length of 4 minutes and 128 kbit/s encoding, resulting in a 4.8 MB file.
2. 1 GB = 1 billion bytes; actual formatted capacity less.
3. Rechargeable batteries have a limited number of charge cycles and may eventually need to be replaced. Battery life and number of charge cycles vary by use and settings.
4. Not all applications are supported.

iTunes 2: How to Burn an MP3 CD

With iTunes 2, you can burn and read MP3 Audio CDs.
This article has been archived and is no longer updated by Apple.

About MP3 CDs

Using iTunes 2.0 or later, you can burn a disc as an MP3 CD. MP3 CDs can hold 150 songs (about 10 hours of music) on a single CD-R disc. Typical audio CDs can only hold about 15 songs, or 74 to 80 minutes of music. (MP3 CDs hold more songs because the songs are compressed.)

You can play MP3 CDs on other computers and on consumer CD players that are compatible with the MP3 CD format.

How to burn an MP3 CD

iTunes 2 automatically gives you the option to create an MP3 CD whenever you burn a playlist that exceeds the length of a standard audio CD (74 or 80 minutes, depending on the CD-R type.)

Follow these steps to set up iTunes 2 to always burn MP3 CDs:

1. Choose Preferences from the iTunes menu (Mac OS X) or Edit menu (Mac OS 9).
2. Click the CD Burning tab.
3. Click MP3 CD to enable that option.

Note: An MP3 CD will only appear in iTunes' Source list if it was created with iTunes 2. MP3 CDs created with another application or device will not appear in the Source list, but will appear on the desktop as a data disc.

Additional information

To learn how to set the play order of songs on an MP3 CD, see technical document 60931 "**iTunes 2: How to Set the Play Order of Songs on an MP3 CD**".

iTunes 2: When Radio Tuner Listings Are Refreshed

iTunes 2 connects to the Internet to refresh the Radio Tuner listings in three instances outlined in this document.
This article has been archived and is no longer updated by Apple.
iTunes 2 connects to the Internet to refresh the Radio Tuner listings in these three instances:

1. When you click Refresh.
2. When you click Radio Tuner in the Source list for the first time, or when you reinstall iTunes 2.
3. When you click on a stream's disclosure triangle for the first time.

iTunes 2: How to Adjust Sound Enhancer

Sound Enhancer is a feature introduced with iTunes 2
This article has been archived and is no longer updated by Apple.

About Sound Enhancer

Sound Enhancer is an Apple-developed digital sound processing technology introduced in iTunes 2 that adds additional life and richness to audio playback, improving the listening experience with headphones and with external speakers.

How to Adjust Sound Enhancer

Sound Enhancer is turned on by default. You can adjust the level of Sound Enhancer by following these steps:

1. Choose Preferences from the iTunes menu (Mac OS X) or Edit menu (Mac OS 9).
2. Click the Effects tab.
3. Slide the fader between low and high to adjust how much Sound Enhancer is applied to your music.
4. Click Sound Enhancer to deselecting the checkbox and turn Sound Enhancer off.

iTunes 2: Radio Tuner Temporarily Hidden While iPod Updates Music Library

The iTunes Radio Tuner is temporarily hidden while your iPod automatically updates the music library.
This article has been archived and is no longer updated by Apple.

Symptom

The Radio Tuner is hidden whenever your iPod automatically updates the music library.

Solution

Wait until the update is complete before using the Radio Tuner.

Published Date: Feb 18, 2012

iTunes 2: Audio CD Skips When Played on Iomega Predator Drive

Use the computer's internal disc drive to play audio CDs with iTunes 2.
This article has been archived and is no longer updated by Apple.

Symptom

When you play an audio CD in an Iomega Predator drive, songs may skip.

This symptom does not happen with previous iTunes 1, or when you play MP3 CDs.

Solution

Use the computer's internal disc drive to play audio CDs.

iPod: Computer Stops Responding if Put to Sleep When iPod Is Connected

Your computer may stop responding ("freeze") if it goes to sleep with an iPod connected to it.
This article has been archived and is no longer updated by Apple.

Symptom

The computer stops responding ("freezes") if it goes to sleep with an iPod connected to it.

Solution

1. Restart the computer (if necessary).
2. Do not put the computer to sleep when the iPod is connected.
3. Turn off sleep in the Energy Saver control panel (Mac OS 9) or the Energy Saver pane of System Preferences (Mac OS X).

Reset iPod. See technical document 61705, "**iPod: How to Reset**" for steps to reset your iPod.

Note: When you reset iPod all your music and data files are saved. Some customized settings may be lost.
Published Date: Feb 18, 2012

iTunes 2: About MP3 CD Format

iTunes 2 uses a hybrid Mac OS Extended and ISO 9660 format when it burns an MP3 CD.
This article has been archived and is no longer updated by Apple.
iTunes 2 uses a hybrid Mac OS Extended (HFS Plus) and ISO 9660 format when it burns an MP3 CD. This means that when you use the CD with a Macintosh computer, the disc will appear as a Mac OS Extended volume. When you use the CD with a non-Macintosh computer or an MP3 disc player, it will appear as an ISO 9660 disc.

For information on how to create an MP3 CD in iTunes 2, see technical document 60924 "**iTunes 2: How to Burn an MP3 CD**".

About the ISO 9660 standard

iTunes burns MP3 discs using the ISO 9660 level 2 standard and the Joliet filename extension to that standard. ISO 9660 level 2 allows 32-character filenames that use uppercase Roman letters (A to Z), the numbers 0 to 9, and an underscore. Joliet is an extension to ISO 9660 that allows filenames to use 64 Unicode characters. **Important:** Songs with filenames that use non-Roman characters may only appear as a number: "__.001.MP3", for example.

Notes

1. If you create an MP3 CD in the Finder and drag MP3 files to that disc, the Finder creates an ISO 9660 disc. It does not create a hybrid Mac OS Extended and ISO 9660 disc.
2. An MP3 CD will only appear in iTunes' Source list if it was created with iTunes 2. MP3 CDs created with another application or device will not appear in the Source list, but will appear on the desktop as a data disc.

iTunes: Some Sound Format Files Cannot Be Played on iPod

iTunes 2.0 and later can play some kinds of sound files that iPod cannot play. These file will not be copied to your iPod when you update your music library.
This article has been archived and is no longer updated by Apple.
iTunes 2.0 and later can play some kinds of sound files that iPod cannot play. These file will not be copied to your iPod when you update your music library.

iPod cannot play sound files in these formats:

- snd
- NVF (Nomad voice files)
- QuickTime
- mp2
- mp1

iPod can play sound files in these formats depending on how they are compressed:

- aiff
- wav

iPod 1.3 and later can play mp4 (MPEG4-AAC) files.

iTunes 2: System Requirements

This document outlines the system requirements to use iTunes 2.
This article has been archived and is no longer updated by Apple.
To use iTunes 2 music software, your computer must meet the following system requirements:

Hardware

- iTunes 2 works with all Apple computers that have built-in USB ports
- Using iTunes 2 with iPod requires a computer with a built-in FireWire port
- Audio CD burning requires a supported CD-RW drive

Listen to music

- Mac OS 9.0.4 or later (Mac OS 9.2.1 or later is highly recommended)
- Mac OS X 10.1 with SecurityUpdate10-19-01 installed (1), or later
- Internet connection for CD database

Make an audio CD

- Mac OS 9.1 or later (Mac OS 9.2.1 or later is highly recommended)
- Mac OS X 10.1 with SecurityUpdate10-19-01 installed (1), or later
- Macintosh computer with internal Apple CD recording drive
- A compatible third-party USB or FireWire CD recording drive.

Compatible MP3 players

In addition to iPod, iTunes 2 works with a number of third-party players.

Notes

1. The Mac OS X SecurityUpdate10-19-01 can be installed using the Software Update pane of System Preferences. You can also download it from Apple Featured Software (http://www.apple.com/swupdates/).

Epson LX-800 Printer Connectivity

Can an Epson LX-800 printer be directly attached to a Macintosh?

This article has been archived and is no longer updated by Apple.
The Epson LX-800 is a 9-pin dot-matrix parallel printer. Connecting it to a Macintosh would require the use of an optional serial interface and a driver designed for Epson printers. Many third parties listed in the Menu Library on AppleLink produce drivers for the Epson line of printers.

Published Date: Feb 18, 2012

iPod: How to Navigate Menus

This document explains how to navigate the menus in iPod.
This article has been archived and is no longer updated by Apple.
To navigate the menus in iPod you will only use the Scroll wheel, Menu button and the center Select Button. See Figure 1.

Figure 1: iPod Scroll wheel, Menu button and center Select button

Press the Menu button to go to the main menu or to go back a menu.

To select a menu choice use the scroll wheel to scroll to the item, then press the center Select button.

If there is a right arrow (>) to the right of a menu item, pressing the Select button leads to another list of choices, or a new menu.

While a song is playing you can use the navigation buttons to navigate the menus without stopping the current song. You could change the settings such as Repeat, Contrast, or Sleep Timer. If you navigate to another song and press the center Select button it will stop the current song and start the new song.

Note: The Previous/Rewind and Next/Fast-forward buttons are not used when navigating the menus. They are used to fast-forward or rewind the currently playing song, or to play the previous or next song regardless which menu you might be in.

Macintosh-to-NCR ITX Connectivity

Can a Macintosh communicate with an NCR System 10000 running ITX operating system? If so, can this software control file transfer to a specific disk on the NCR system? If not, do you know of a third-party software package that provides either or both of the capabilities? This request involves a school district decision regarding the use of Macintosh as administrative computers and front ends to their NCR mainframe.

This article has been archived and is no longer updated by Apple.
We contacted the local NCR office to find out what was required in connecting to an NCR system running ITX. They said that a dumb terminal (MacTerminal in VT100 would work) was all that was required for one session. There is special software for the PC world (ITX Windows for PC) that allows multiple connections to the system, but we have been unable to find information on a Macintosh version. The local engineer suggested that you contact Central Dispatch at their local NCR office for detailed information on what is required for their particular system.

Further, we found the following software in the Macintosh Buyer's Guide on AppleLink:

MacQT - Macintosh terminal emulation and file transfer

MacQT (Macintosh Quick Terminal) provides emulation of an ADDS Viewpoint (a.k.a., NCR 7901) and NCR 7900 connected to an NCR host running UNIX or NCR's ITX or other operating system. It lets a user run any program on the host system, just as though they were working on a dumb terminal. Emulation is fast and thorough. MacQT will transfer, in either direction, sequential ASCII files or spool (print out) files. Host software is provided where necessary for file transfer. Contact Rasmussen Software, Inc (check the Technical Info library for details) about MacQt.

iTunes 2: About Connecting Your MP3 Player

You can connect your MP3 player to your Mac to use it with with iTunes 2.
This article has been archived and is no longer updated by Apple.
You can transfer songs from your library to a portable MP3 player, such as the Apple iPod. iTunes works with several players. For the latest information, visit the iTunes Web site.

Connect your MP3 player to your computer with the FireWire or USB cable that came with the device. After a moment, the player's icon appears in the source list. If you are using the Apple iPod and iTunes is set to update it, all your iTunes songs are transferred to iPod automatically.

If your iPod is not set up to automatically update, you can drag songs from the iTunes library or a playlist to the player's name in the source list.

Some players, such as iPod, have additional options. Use the buttons in the lower-right corner to access additional settings.

When you're transferring songs to your player, be sure that your computer does not go to sleep.

For more information about iPod, see iPod Help, or go to www.apple.com/ipod/ .

iTunes 2: Unicode ID3 Tags With Double-Byte Characters Appear as Garbled Text

When using double-byte characters, iTunes 2.0 and 2.0.1 incorrectly format Unicode ID3 tags on songs they encode, and the Unicode tags of songs encoded with other application programs and subsequently edited with iTunes 2.0 or 2.0.1.
This article has been archived and is no longer updated by Apple.

Symptom

When using double-byte characters, iTunes 2.0 and 2.0.1 incorrectly format Unicode ID3 tags on songs they encode, and the Unicode tags of songs encoded with other application programs but edited with iTunes 2.0 or 2.0.1. Tags for these songs appear as garbled text.

iTunes 2.0.2 properly formats Unicode ID3 tags, and automatically corrects the formatting for songs that were encoded by iTunes 2.0 or 2.0.1. However, it does not correct ID3 tags with double-byte characters, for songs encoded with another program and subsequently edited using iTunes 2.0 or 2.0.1. For these songs, iTunes 2.0.2 displays ID3 tags with garbled text.

Solution

If you are using iTunes 2.0 or 2.0.1, download and install iTunes 2.0.2 or later. It is available from the iTunes Web site (http://www.apple.com/itunes/). iTunes 2.0.2 can automatically correct Unicode ID3 tags on songs for tracks improperly encoded with iTunes 2.0 or 2.0.1

If you are using iTunes 2.0.2 and Unicode ID3 tags display incorrectly, you can still play songs without any issues. However, the ID3 tags of songs encoded with another program and subsequently edited using iTunes 2.0 or 2.0.1 will appear as garbled text.

Apple expects to release a version of iTunes with a feature that can manually fix incorrectly formatted Unicode ID3 tags.

MacTerminal: Eliminating the X0 Command

I have discovered that MacTerminal sends out a command that is not always accepted by the telephone company. If you do the automatic dialing, using Dial in the Phone menu, the Macintosh sends the following:

ATS0=0 E0 V0 X0 H0 cr
AT cr
ATDT number cr

The problem is the X0. This puts the modem in a "blind dial mode." In other words, the modem does not wait for a dial tone before it starts to dial. This doesn't always work, depending on what kind of telephone system there is.

Is there any way of changing this command sequence, so that MacTerminal doesn't send X0?

This article has been archived and is no longer updated by Apple.
To change the X0 in MacTerminal's dial string to an X2 or X4 requires the use of a file editing utility such as FEdit or SEdit. Make a working copy of MacTerminal first, and open it from the utility. Do an ASCII search for "ATS0" (the 0 is a zero). Within one block, there should be two occurrences of "ATS0=0E0V0X0H0". Edit the "X0" to "X2", being careful not to add any extra text. Write the sector back to disk.

It would also be a good idea to modify MacTerminal's version resource, so that users can easily tell this copy has been modified. Using ResEdit, open MacTerminal's vers resource ID#1. Modify two strings as follows:

Abbreviated string "2.3.1"
Change it to "2.3.1.x2"

Get Info string "2.3.1 Copyright c Apple Computer, Inc. 1983-1989"
Change it to "2.3.1.x2 Copyright c Apple Computer, Inc. 1983-1989"

Remember that this is an unsupported patch, and could cause problems if MacTerminal encounters result codes it doesn't expect. By changing the X0 to X2 or X4, you immediately expand the set of result codes that MacTerminal may see. If it doesn't handle these well, the results can be unpredictable.

iPod: "Storage device was not properly put away" Alert When You Disconnect FireWire Cable

When FireWire disk mode is turned on, an alert box appears if you disconnect iPod without first choosing Put Away (Mac OS 9) or Eject (Mac OS X) from the File menu, or clicking the eject button in iTunes.
This article has been archived and is no longer updated by Apple.

Symptom

When you disconnect iPod's FireWire cable, an alert box appears with one of these messages:

Mac OS X 10.1
"The storage device that you just removed was not properly put away before being removed from this computer. Data on the device may have been damaged or lost. In the future, please put away the device (Choose its icon and Eject it or Drag it to trash) before removing the device."

Mac OS 9
"A FireWire disk has stopped responding. The problem must be corrected to prevent damaging the disk's contents. Please check all FireWire connections. If you added, removed, or turned a FireWire device on or off, try undoing what you did."

Solution

You should always put away iPod's hard disk icon before disconnecting the FireWire cable. Follow these steps.

Mac OS 9

1. Reconnect the FireWire cable to iPod. The alert box is dismissed.
2. Put away the iPod hard disk icon by dragging it to the Trash, or click its icon and choose Put Away from the file menu or Eject from the Special menu. You can also use the keyboard shortcuts by pressing the Command-Y keys or Command-E keys. In iTunes you can select iPod in the playlist and click iTunes' eject button.

Mac OS X 10.1

1. Click OK to dismiss the alert.
2. Reconnect the FireWire cable to iPod.
3. Put away the iPod hard disk icon by dragging it to the Trash, or click its icon and choose Eject from the File menu. You can also use the keyboard shortcut by pressing the Command-E keys. In iTunes you can select iPod in the playlist and click iTunes' eject button.

iTunes 2.0: "Preferences could not be displayed" Alert

If you have a large number of files in your music library, you may need to increase iTunes memory allocation to set preferences or use iPod.
This article has been archived and is no longer updated by Apple.

Symptom

When you click the Effects, Import, or Burn tabs in the iTunes Preferences panel, an alert box with this message appears:

> "The application preferences could not be displayed because there isn't enough memory available. Try quitting other running applications or quit iTunes and increase its preferred memory setting."

Solution

The iTunes music library can list approximately 32 000 songs. If you have a lot of songs and experience slow performance, if you use iPod, or if alerts like the one above appear, follow these steps:

- Quit open applications that you are not using to make more memory available to iTunes.
- Increase iTunes preferred memory setting:
    1. Quit iTunes, if necessary.
    2. Select the iTunes application program icon.
    3. Choose Get Info from the File menu.
    4. Choose Memory from the Show pop-up menu.
    5. Make the Preferred memory larger, and close the window.
    6. Repeat step 5 if alerts continue to appear.

Microsoft Word: Repairing Corrupted Documents

I have designed a table/chart in Microsoft Word 4.0. Superpaint 2.0 was used to rotate some of the headings and insert large bullets.

When printing the document, I get the beginning of the table in Palatino (the desired font) and Helvetica, but later in the document the Palatino font is being replaced by Courier. I checked "no font substitution," but got the same result. The chart printed fine with LaserWriter 5.2, but this problem occurs with LaserWriter 6.0 or above. What happened with the new version of the driver?

This article has been archived and is no longer updated by Apple.
When we printed your document here, it printed incorrectly every time--not only with LaserWriter 6.0 and 6.0.1. This suggests that the problem is some type of file corruption.

When a Microsoft Word file is corrupted, Microsoft suggests saving the file under a different name in RTF format, closing it, opening it again, and saving it again in regular Microsoft Word 4.0 format. When opening the RTF format file, Microsoft Word will ask if you would like to convert the file from RTF to regular Microsoft Word format. Say yes. This process will take a few minutes.

We tried this process with the file you sent, and all tables in the document printed with the correct font (Palatino).

DVD Player 3.0.1: Unexpectedly Quits When You Use 256 Colors

Using DVD Player 3.0.1 while the display is set to 256 colors can cause the application to unexpectedly quit. In Mac OS X the option for 256 colors is unavailable on most systems. It is available on the Power Macintosh G3 (Blue and White) computer, and may be available on systems with third-party video cards that did not come with the computer.

This article has been archived and is no longer updated by Apple.

Symptom

DVD Player unexpectedly quits if the display is set to 256 colors.

Solution

1. Choose System Preferences from the Apple menu.
2. Click Displays.
3. Choose thousands or millions from the Colors pop-up menu.

Published Date: Feb 18, 2012

iTunes 2: iPod Does Not Appear in Source List

If iTunes 2 is installed on a volume that is not used as the startup disk, iPod will not appear in the iTunes Source list.
This article has been archived and is no longer updated by Apple.

Symptom

iPod doesn't appear in the iTunes Source list even though you've connected it to the computer. This occurs when iTunes 2 is installed on a volume that is not used as the startup disk. If iPod displays this symptom, and iTunes is installed on the startup disk, see technical document 60950: "**iPod: Not Recognized in iTunes and/or Finder**".

Solution

Reinstall iTunes 2 so that it is in the Applications folder on the startup disk. iTunes 2 cannot recognize iPod if it is installed on a partition or volume other than the startup disk. Later versions of iTunes will only install on a startup volume and are not affected.

A/UX 2.0: and dbm.h

I am working with a Macintosh IIfx with HD80 SC and 8MB RAM and A/UX 2.0. My group is currently operating an AT&T System V system and evaluating A/UX as a replacement for their current system. As part of this evaluation, we are taking their code and re-compiling it under A/UX 2.0. All of these questions concern the operation of the dbm function under A/UX 2.0.

1) Because dbm.h redefines null, it is a problem using standard I/O calls. Any workarounds available?

2) The dbm.h file lists several functions not described in the manual such as:
- makedatum
- calchash

3) The fetch function under dbm is described in the manual to return a pointer to data. However, in the dbh.h file, it is described as returning the data itself. Which is true?

This article has been archived and is no longer updated by Apple.

```
1) dbm.h redefines null to be a pointer instead of just 0, but nothing says
that you can't redefine it yourself within your function that wants to use
standard I/O library calls.  Or redefine your own NULL and use it as your NULL
reference.  Without specific examples, it's hard to give you a specific
workaround.

2) Anything you find in a header file that is not documented or obvious as to
its function is usually an internal declaration used for the program itself.
This is the case with the extra function declarations in the dbm.h file.

3) The fetch function returns the data itself, not a pointer to it.
```

ATalk Phase 2: Extracting Zone Multicast Addresses

I manage a large Ethernet network supporting Macintoshes and VAX systems. To manage the network traffic, we want to install filtering bridges to contain multicast packets within defined parts of the internet.

I understand that the Ethernet destination address for AppleTalk Phase 2 isn't broadcast, and zone multicasts are supported. How do you get access to the zone name/multicast address mapping for the Internet, as this is held within the bridges in the ZIT (Zone Information Tables)? We would need to dump the ZIT so that the bridge can be configured, but I can't find any utility that will extract the zone table from the Internet router. Do you know how this can be done?

This article has been archived and is no longer updated by Apple.
There are no utilities that we know of to extract the zone multicast address from the routers of AppleTalk Phase 2 networks. You could use any of the new Macintosh-based Ethernet monitor programs (EtherPeek from the Avant Garde Group or Netminder from NEON Software) to extract the information.

There may be some problems even after you have the data. Zone multicast addresses are assigned on a dynamic basis, using an algorithm that gets the seed number of the multicast address from the zone name itself. If the zone names were changed, the multicast address could also change. There is also a problem where different zones can be assigned the same multicast address, in which case if you blocked one zone you would block all zones that are assigned to that multicast address.

I think you will find a small savings in packet traffic for the amount of work involved in setting up this non-standard approach to segmenting their network. Zone multicast traffic accounts for only a very small amount of the over all traffic present on the net. If you really want to segment your traffic, look at installing some Ethernet-based routers instead of the bridges. Routers are a much cleaner way of isolating network traffic in such situations.

You could also program their bridges to isolate all of the AppleTalk multicast addresses; the addresses start at 0x090007000000 and end at 0x0900070000FC. 0x0900007FFFFF is also used as the general AppleTalk broadcast address.

Final Cut Pro: Do Not Use High ASCII Characters In FXScripts

If copyright (©), registered (®), or other special characters are used in FXScripts on systems using double-byte text, an alert box with this message appears: "FXScript Error: Missing 'code'". To eliminate this issue, the special characters should be removed from the script.
This article has been archived and is no longer updated by Apple.

Symptom

An alert box with this message appears:

> "FXScript Error: Missing 'code'"

Solution

Do not use high ASCII characters when creating FXScripts.
Published Date: Feb 18, 2012

Final Cut Pro 3: After Effects Plugin Presets Have No Effect

Some After Effects plugins include several presets settings. In some circumstances selecting those presets has little or no effect.
This article has been archived and is no longer updated by Apple.

Symptom

Selecting an After Effect plugin preset produces unexpected results.

Solution

Apple is seeking a solution to this issue. You can avoid this issue by ensuring that frames of the clip you are trying to apply the effect to are not shown in the Canvas or Viewer. You can either close the Canvas and/or Viewer windows or move the playhead in the timeline to another clip.
Published Date: Feb 18, 2012

Final Cut Pro: Title Safe Boundaries Change With Window Size

If you use the Text Generator in Final Cut Pro you may notice the Title Safe area is not consistent when changing canvas size. The Text Generator seems to violate the Title Safe area when viewed at 100 percent but not at smaller percentages.

This is only cosmetic. Once the text is rendered you will notice during playback it actually is within the Title Safe area.
This article has been archived and is no longer updated by Apple.

Symptom

The Text Generator seems to violate the Title Safe area when viewed at 100 percent but not at smaller percentages.

Solution

Render the text so that the Title Safe area is accurate. Apple is seeking a solution to this issue.

Final Cut Pro 3: Bold Effects May Not Be Available for Software Real-Time

Effects and transitions that appear in bold in the Effects menu or Effects tab in the Browser may not be available for software real-time playback. The number and kinds of effects available for software real-time depend on the performance of the computer.
This article has been archived and is no longer updated by Apple.

About real-time effects

If you have a Power Mac G4 or PowerBook G4 that is qualified for G4 real-time Effects as outlined in the product specification, please be aware that products at the lower end of the speed range may not be able to preview all effects in real-time. Not all boldfaced items are available for real-time preview on all computers. Boldfaced items should be taken to represent the range of real-time effects that is possible at the highest end. This is the intended behavior of the program.

In order to check that G4 real-time effects are available on your computer (in either OfflineRT format or DV format) insert a static graphic into the Timeline. A static graphic may be text or a freeze frame made from a video clip that matches the resolution of the format you are working in. Real-time preview of a static graphic is available on any computer on which G4 real-time effects are available.

If a green render bar is visible in the Timeline, then your computer is properly set up for software real-time previews. If a static graphic is not available for real-time preview, your computer may not be properly set up. Refer to the manual for setup instructions.

Symptom

Effects and transitions appear in a bold face font, but have a red render bar when placed in the timeline.

Solution

OfflineRT is a suitable alternative to those seeking G4 real-time effects, but with computer that are not capable of using a wide range of the possible effects on their computer in the DV format. OfflineRT is designed with mobile editing in mind, and is the best format for those seeking G4 real-time effects on a PowerBook.

In Final Cut Pro 3.0.2 and later, the bold real-time effects listed in the Effects menu are accurate for each specific computer. The menu items are bold only if your computer can use real-time effects.

Applesoft: Numeric Comparison Issues

When two numbers print as equal, though an IF statement indicates they're not, the least significant bits in the internal binary storage format of those numbers are different.

Also, sometimes Applesoft's math package doesn't give the answer you expect because Applesoft calculations are done in a 32 bit binary floating point format, which have no exact equivalents to most numbers.
This article has been archived and is no longer updated by Apple.
Applesoft's PRINT statement truncates a number that is extremely close to being an integer. For example, 3^2 and 3*3 will both print as 9 but won't compare as equal. Printing 3^2 - 3*3 will result in 3.7252903E09, while the expression 3^2 = 3*3 is false.

Also, Applesoft uses natural logarithms to calculate many of its trancendental functions, which adds small errors to the results.

To avoid comparison problems, round Applesoft real numbers to a specific number of decimal places.

Use the formula: X = INT(X*P+.5)/P

where P=10 for 1 decimal place, P=100 for 2 decimal places and P=1000 for 3 decimal places, etc.

Apple II Silentype manual A2L0034/030-0095-00: Errata

This article has been archived and is no longer updated by Apple.

Page 11... The procedure for printing a High-Res image doesn't work, since Pascal clears the High-Res buffer when you go to the Filer. We suggest modifying the program as shown below:

```
Program Sprio;

USES Turtlegraphics, Applestuff;
Var angle, distance : integer;
CH : Char; (* added *)

Begin
angle := 0;
While not Keypress Do
Begin
InitTurtle;
Pencolor (white);
For distance := 0 to 99 Do
Begin
Move (2 * distance);
Turn (angle);
End;
angle := angle + 5;
End;
CH:=CHR (17); (* added *)
Unitwrite (6,CH,1,0,12); (* added *)
Textmode
End.
```

Page 13...The discussion on "Echoing to the screen" assumes that you have already done a PR#1 before you do the T command.

Page 18...The discussion in the last paragraph assumes that you have already done a PR#1 before you do the Q command.

Page 38...Line 4, "for the right margin is 2" should be "for the left margin is 2"

Page 39...Program line 6040 should end with Then Goto 6070

iPhoto: How to Spell Check

This document explains how to use the Spell Check feature in iPhoto.
This article has been archived and is no longer updated by Apple.
To spell check in iPhoto:

1. Select a text box.
2. Choose Spelling from the Edit menu, then choose Check Spelling from the submenu.
3. Repeat steps 1 and 2 for each text box.

Important: Only the selected text box is checked--not the entire page or document.

Final Cut Pro 3.0: "Out of memory" Alert When Importing Photoshop Files

Final Cut Pro 3 for Mac OS X does not import Photoshop files that have empty layers, and an alert box may appear with an "Out of memory" message.

This article has been archived and is no longer updated by Apple.

Symptom

When you import a Photoshop file an alert box with this message appears:

> "Out of memory"

The file is not imported.

Solution

Use one of these solutions:

- Delete empty layers from the Photoshop files.
- Use Final Cut Pro for Mac OS 9.

iPhoto 1.0: External Editing Application Does Not Open Photo

If you have selected an external editing application in iPhoto preferences, the application may not open the photo when you double-click it in iPhoto if you have changed the photo's filename in the Finder.
This article has been archived and is no longer updated by Apple.

Symptom

Double-clicking a photo in iPhoto opens the external editing application, but the photo does not open inside that application.

Solution

This issue may be caused if you changed the photo's filename in the Finder. Change the filename back to the original to resolve the issue.

Final Cut Pro 3: QuickTime Version Remains 5.0.2

Final Cut Pro 3 requires and includes QuickTime 5.0.4. However, you may notice after installing QuickTime 5.0.4 that the QuickTime version remains at 5.0.2.
This article has been archived and is no longer updated by Apple.

Symptom

QuickTime version says 5.0.2 even though 5.0.4 has been installed.

Products Affected

- Final Cut Pro 3
- QuickTime 5.0.2

Solution

Because QuickTime 5.0.4 only updates two lower level components, the version reported by the QuickTime Settings control panel in Mac OS 9 and the QuickTime pane in System Preferences in Mac OS X will still state version 5.0.2.

You can be assured that QuickTime 5.0.4 is installed correctly if the Final Cut Pro 3 application opens successfully. If QuickTime 5.0.4 or later hasn't been properly installed, the application will notify you, then quit.

Auto-Restart after Power Failures: An ADB Device

Is there any way to restart a Macintosh II, Macintosh IIx, or Macintosh IIfx server after a power failure?

This article has been archived and is no longer updated by Apple.
There is no software that restarts a Macintosh after a power failure. However, we heard of a new ADB device that restarts a Macintosh after a power failure--just the thing for a remote server or router. It is called JumpStart, from ARCOM. For more details, search the Technical Info library under "ARCOM Electronics Inc."

iTunes: "Error -208 Cannot Open iTunes Music Library" Alert

The iTunes Music Library file may be unusable if an alert box with the message "Error -208 Cannot Open iTunes Music Library" appears.
This article has been archived and is no longer updated by Apple.

Symptom

An alert box with this message appears:

> "Error -208 Cannot Open iTunes Music Library"

Solution:

1. Find the iTunes Music Library file. In Mac OS 9, this file is normally located in the iTunes folder in your Documents folder. In Mac OS X, the iTunes Music Library is located in either the Documents or Music folders. These folders are located in your Home folder; choose Home from the Finder's Go menu.
2. Drag the iTunes Music Library file to the Trash.
3. Optional: Find the "com.apple.iTunes.plist" file in your Preferences folder (~/Library/Preferences) and drag it to the Trash. This will reset your iTunes preferences, and cause the iTunes Setup Assistant to open so iTunes can search for all your music files again.
4. Open iTunes. A new iTunes Music Library file is created. You may need to recreate your playlists, and manually add music files back into your library.

iPhoto: Revert to Original Dimmed After Editing With an External Editor

After editing a picture with an external editor, the Revert to Original command is dimmed in the File menu.
This article has been archived and is no longer updated by Apple.

Symptom

Revert to Original is dimmed in the File menu after you edit a photo with an external editor.

Solution

1. Import a picture into iPhoto.
2. Crop the picture within iPhoto.
3. Use the external editor to perform other edits.
4. Revert to original is no longer dimmed.

Published Date: Feb 18, 2012

iPhoto: Thumbnail Does Not Update After Photo Is Edited

After editing and saving a photo with an external editor, the thumbnail in iPhoto does not update to show the edits.
This article has been archived and is no longer updated by Apple.

Symptom

After editing and saving a photo with an external editor, the thumbnail in iPhoto does not update to show the edits.

Solution

Follow these steps to update the thumbnail:

1. Select the photo that you want to edit.
2. Edit the photo with the external editor application.
3. Save changes.
4. With the photo still selected, click Edit in iPhoto.
5. Click any of the iPhoto edit functions (Red Eye, for example).
6. Choose Undo from the Edit menu.
7. Click Organize.

The thumbnail should now be updated.
Published Date: Feb 18, 2012

Final Cut Pro 3: Issue Capturing Timecode Beyond Hour 23

Capturing video with timecode that extends beyond 23:12:00;00 can result in media with incorrect timecode information.
This article has been archived and is no longer updated by Apple.

Symptom

Batch captured clips appear with no media connected. Trying to import the clip results in "File unknown" alert. Reconnecting the clip results in no connection to media. Capture displays hour 0 as its current timecode.

Solution

Final Cut Pro 3.0.4 addresses this issue. The update to Final Cut Pro 3.0.4 is available from this document "**Final Cut Pro 3.0.4 for Mac OS X: Information and Download**."

If you are unable to update to Final Cut Pro 3.0.4 at this time, then there are several options available listed below.

Capture the video using Capture Now. Capturing in this way results in a timecode track that is always 0, which is undesirable if you will need to recapture any of your clips (if you're doing an online edit, for example).

OR

Duplicate the tape to another tape with new timecode. This requires two compatible video decks and incurs generation loss if analog I/O is used.

OR

Restripe the timecode if your video deck has this capability.

iTunes 2: How to update Rio firmware

You can use iTunes 2 to update the firmware on a Rio MP3 player.
This article has been archived and is no longer updated by Apple.
If you have a Rio MP3 player, you can use iTunes to update its built-in software.

1. Connect the Rio to your Mac, then select the Rio in the source list.
2. Click the Options button in the lower-right corner of the iTunes window.
3. Click Upgrade Firmware, then choose the upgrade file you obtained from the manufacturer.

Firmware updates are available occasionally, and may not be necessary for all Rio models. See the SonicBlue Web site for information about your device.
Published Date: Feb 18, 2012

iTunes 2: About the symbols next to songs

When you import songs and work with playlists, symbols next to songs show their status.
This article has been archived and is no longer updated by Apple.
A moving zigzag means a song is being imported. A green checkmark means iTunes has finished importing the song.

An exclamation point means the song file can't be located. It may have been moved or deleted.

A globe means the song is stored on the Internet, and "streamed" to you (via the Internet) when you click to play it.

A black checkmark means the song will be included in your next action. For example, only songs with black checkmarks are imported.

A speaker means the song is currently playing. When importing a song you're also listening to, you see a moving zigzag instead of the speaker.

When you eject a CD, the symbols disappear. For more status information, watch the display at the top of the iTunes window.

MacDFT: IBM 4700 Connectivity

I have installed MacDFT with the Apple Coax/Twinax Card. I am interested in setting up a 4700 connection using MacDFT also. Tests have gone well, apart from some problems related to the keyboard. For instance, the string generated from a Clear in a 4700 configuration is different from the one generated from a 3278.
This article has been archived and is no longer updated by Apple.
The 4700 series of Control Units are specialized controllers sold by IBM, typically to banks. This series includes the 4700, 4701, and 4702. The 8770 Control Unit is also a specialized controller sold by IBM to finance companies. These are specialized controllers, and there is no stated support for them with MacDFT.

One solution might be to set MacDFT up for CUT mode emulation. When MacDFT is in CUT mode, much of the terminal and communication processing is done by the controller. In this case, this may help eliminate or minimize any keyboard mapping discrepancies.

It is also possible there is an RPQ installed, which is a specialized remapping program. When using RPQ, you can usually go back to any "default" key by pressing "Alt" and the appropriate key. For example, to execute a Clear when using a RPQ, press Alt and Clear. With MacDFT, because the Alt key isn't mapped, you'll need to assign a key to the Alt-Clear sequence using the Keyboard mapping feature. This is documented in Chapter 5 of the "MacDFT User's Guide."

Other companies use a different strategy with RPQs. DCA sells different keyboard layouts for the Macintosh for some of the different RPQs commonly used.

If no RPQ is installed, you might be able to remap any errant keys using the keyboard mapping feature anyway.

iTunes 2: How to add a music file to your library

If you have an MP3 file that you've downloaded or obtained elsewhere, you can add it to your music library.
This article has been archived and is no longer updated by Apple.
Drag the MP3 file to the library.

A reference to the file is added to the library, but the file is not copied or moved. If you drop a folder or disk on the Library, all the audio files it contains are added.
Published Date: Feb 18, 2012

iTunes 2: How to organize your music library

The library is where you find and organize the songs you've imported into iTunes.
This article has been archived and is no longer updated by Apple.

1. Click the Browse button to display a list of all your songs, organized by album and artist.
2. To sort the list, click the column heading. (For example, click Song to sort by song title.)
3. To reverse the sort order, click the triangle in the selected column's heading.
4. To rearrange the columns, drag the headings into the order you want. To resize a column, drag the borders between the column headers.
5. To display the musical genre of an album when you're browsing, choose Preferences from the iTunes application menu. Then click Show Genre When Browsing in the General pane.

Published Date: Feb 18, 2012

iTunes 2: How to add songs from CDs to your music library

You can add songs from your favorite CDs to the library. Songs are encoded and stored on your hard disk so you can listen to them without having the original CD. The default encoding format is MP3.
This article has been archived and is no longer updated by Apple.

1. For the best performance and results, use the computer's internal CD drive to import songs.
2. Insert an audio CD in your Mac. After a moment, the songs on the CD are listed in the iTunes window.
3. Click to remove the checkmark next to any songs you don't want to add to your library.
4. Click the Import button to add the selected songs to your library. The display area at the top of the iTunes window shows how much time it will take to import each song, compared to the time it takes to listen to the song. To cancel import, click the small X next to the progress bar.

iTunes plays songs while they're being imported. Click the Pause button to stop playback; the import will continue. You can work with iTunes while songs are being imported.

UNIX: Access to Macintosh File System

Do we have any documentation of what type of access is available in A/UX 2.0 to access the Macintosh side from UNIX applications? This would include writing programs or shell scripts that manipulate Macintosh programs or data in a Macintosh file system.

This article has been archived and is no longer updated by Apple.

You can write hybrid applications that can access Macintosh volumes but retain a UNIX interface. To do this, you must use the calls provided in the Toolbox. These calls are documented in "Inside Macintosh" with the differences documented in the "A/UX Toolbox" manual.

Standard Macintosh applications can, of course, use both UNIX and Macintosh file systems simply by making the standard Macintosh File Manager calls. If these calls are used to access a UNIX file system, they are mapped internally to the appropriate UNIX routines instead, without the Macintosh application being aware of any differences.

On the other side, UNIX programs cannot see or use the Macintosh volumes. The "ls" binary is a perfect example of this. Because it was written using the standard UNIX libraries, it cannot access any Macintosh volumes. Because of this, shell scripts are also incapable of accessing Macintosh volumes. It is conceivable that you could write your own version of "ls" that uses the Toolbox but retains the same interface as the existing command. At that point, you could then use the command from within a shell script.

The A/UX Development Tools product is a full development package supporting this type of development.

LaserWriter IINTX: Setting the Mode Software Switch

The new LaserWriter IINTX ROMs apparently allow software switching between the AppleTalk and RS-232 input modes. Has anyone written these files?

This article has been archived and is no longer updated by Apple.
Yes, the new version of the "LaserWriter IINT/NTX Owner's Guide" details the commands necessary to switch modes. This manual is included with new LaserWriter IINTX models, and with all ROM upgrades. Appendix C of the manual, "Connecting to and Printing with an MS-DOS Computer," covers this and related issues in relative detail. We definitely recommend reading it, but below we have copied some of this section, which should be useful to you.

Although the section assumes use of a DOS computer, the PostScript code is the same for a Macintosh. Simply remove the DOS specific lines and download the file with the LaserWriter Font Utility.

Selecting an operating mode

If you have a LaserWriter IINT:

*** Details on setting the LaserWriter IINT modes omitted ***

If you have a LaserWriter IINTX:

There are two ways to set the LaserWriter IINTX operating mode:

- You can use the DIP switches to set the mode.

- You can use software switching (sending a program to the printer) to set the mode. Software switching works only with LaserWriter IINTX printers that use PostScript Rev 3.0 or later. Check your printer's startup page to see what Rev it uses.

If you plan to set the printer mode once or infrequently, use the DIP switches to set the mode. If you plan to change operating modes frequently, you should use software switching to set the mode. Both methods are described here.

Setting the Mode with DIP Switches

You can set the LaserWriter IINTX to work in PostScript mode, to emulate a Diablo 630 printer, or to emulate a Hewlett-Packard LaserJet+ printer. Set the switches on the LaserWriter IINTX as follows.

PostScript Mode

If you plan to use software that supports PostScript, switch 2 should be down, and switches 3 and 4 should both be up. Switch 1 can be up or down.

Diablo Emulation

If you plan to use the Diablo emulator, switches 2 and 3 should be down and switch 4 should be up. Switch 1 can be up or down.

LaserJet+ Emulation

If you plan to use the LaserJet+ emulator, switches 2, 3, and 4 should be down. Switch 1 can be up or down.

Setting the Mode with Software Switching

Software switching can be used to set both the software mode used by the printer (PostScript or an emulator), and the hardware mode used by the printer (serial or AppleTalk).

To change the software mode using software switching, you send a program to the printer that changes a value called softwareiomode. To change the hardware mode using software switching, you send a program to the printer that changes a value called hardwareiomode.

The LaserWriter IINTX supports four values for softwareiomode:

0 (PostScript batch mode)
1 (PostScript interactive mode)
2 (Diablo 630 emulation)
5 (HP LaserJet+ emulation)

The LaserWriter IINTX supports two values for hardwareiomode:

0 (serial communication)
2 (the AppleTalk communication protocol)

To use software switching to select a hardware and software operating mode, type the following PostScript program at the DOS prompt and send the program to the LaserWriter IINTX:

```
cd \\
copy con set.mod
(Macintosh file begins here)
serverdict begin 0 exitserver
statusdict begin
S setsoftwareiomode
H sethardwareiomode
(Macintosh file ends here)
Control - Z
```

Instead of typing S in the line where it appears in the program, type the value for the software mode you want to set (0, 1, 2, or 5).

Instead of typing H in the line where it appears in the program, type the value for the hardware mode you want to set (0 or 2).

The program that changes your hardware and software modes is now saved in a file called SET.MOD. To send the program to the LaserWriter IINTX, type this line at the DOS prompt:

```
type SET.MOD > COM1
```

Substitute COM2 for COM1 in the line above if the LaserWriter II is connected to the COM2 port on your computer.

Typing the line given above and pressing return sets the software and hardware operating modes on the LaserWriter IINTX.

Switching from an Emulator to PostScript on the LaserWriter IINTX

There is a quick way to switch from either the Diablo 630 emulation or the LaserJet+ emulation and go into PostScript batch mode. Simply type into a file the command sequence Escape-Delete-Zero, followed by a Control-D, and print the file to the LaserWriter II. When you send this file, the LaserWriter II resets itself to PostScript batch mode.

Published Date: Feb 18, 2012

You‘re unable to burn a CD in iTunes

Check hardware
This article has been archived and is no longer updated by Apple.

To create audio CDs with iTunes, you must have a compatible CD-RW drive and Mac OS X 10.1 or later (Mac OS X 10.1.5 or later is recommended).

All Apple internal CD-RW drives work with iTunes. To see if iTunes works with an external drive, choose **Preferences** from the **iTunes** menu, then click the CD Burning tab. If your drive is listed, it will work with iTunes.

Make sure your computer and display are not set up to go to sleep.

If you've made a CD and it seems to stutter when played back in your external CD-RW drive, try playing it in your internal CD drive or in a stereo system. Some external drives may not play CDs properly.

If your CD burn is unsuccessful and your external drive becomes unresponsive, turn it off and on to reset it.

Make sure your burner is listed as a device or volume in Apple System Profiler. If not, check to make sure it is connected correctly and set up to burn discs.

Check iTunes settings

If you have set the Gap Between Songs to 5 seconds in iTunes preferences, try setting it to something shorter, such as 2 seconds.

Make sure you've chosen the correct disc format for the files you're trying to burn to your CD or DVD. To create an audio CD, you need to choose Audio CD in the Burning pane of iTunes preferences. To create a CD with any type of audio file that iTunes supports (MP3, AAC, AIFF, and so on), you need to choose "Data CD or DVD" in the Burning pane of iTunes preferences.

Songs that aren't selected are not burned to a disc and are dimmed during a burn. If none of the songs in a playlist are selected, you will see the alert "None of these items in this list can be burned to CD."

Set the burn speed in iTunes to 2x:

1. From the **iTunes** menu (Mac OS X) or **Edit** menu (Mac OS 9), choose **Preferences**.
2. iTunes 5: Click the Advanced tab and then click the Burning tab. iTunes 3 and 4: Click the Burning tab.
3. Choose 2x from the **Preferred Speed** pop-up menu. If the burn is successful, keep trying a faster burn speed until you are unable to burn successfully, then set the burn speed to the last successful speed.

Check CD media

Use a different brand of CD media that is 74 or 80 minutes long. Apple sells blank CDs at the Apple Store that should work with iTunes. Click on Music to find the discs.

If you are using CD-RW (instead of CD-R) discs, only use CD-RW discs that are rated from 1x to 4x speed.

Update your software

For Mac OS X, use Software Update to make sure you have the latest version of Mac OS X and iTunes.

For Mac OS 9, use Software Update to make sure you have the latest versions of Mac OS 9 and Authoring Support.

Quit other applications

Quit all other open applications before burning a CD.

Quit the Classic application environment in Mac OS X. You can do this in the Classic pane of System Preferences.

Allow the drive to complete the burn before you do anything else with the computer. Wait to browse the Internet or listen to music with iTunes until the burn is complete.

Other things to check

If your playlist includes songs that were purchased from the iTunes Store (iTunes 4 only), you can only burn 7 copies of the same playlist to an audio CD. If you can't burn a CD that contains purchased songs, make sure you haven't tried to burn the same playlist 7 times. Additionally, if the song has not been authorized to play on the computer, it will not burn.

When you insert a blank CD, a message asks you to continue, eject, or initialize the volume (disc). Click Continue, then click the Burn button in

iTunes to create the CD. To avoid this message, click the Burn button before inserting a blank CD.

If you can't eject a blank CD after you've inserted it, click the Eject button in iTunes.

Tips for external USB CD-R burners

In addition to the steps above, try these additional steps if you have an external USB CD-R burner.

To create CDs with a USB CD-RW drive, set the burn speed in iTunes to 2x. Choose **Preferences** from the **iTunes** menu (Mac OS X) or **Edit** menu (Mac OS 9), then click Advanced tab (iTunes 5) and then the Burning tab. Choose **2x** from the **Preferred Speed** pop-up menu.

Disconnect all other USB devices except the mouse and keyboard.

If you are using a USB hub, disconnect it, and connect the drive directly to the computer's built-in USB port.

Sending SunView to MacX Server

Article Change History

01/15/93 - REVIEWED
* For technical accuracy.

I was trying to install MacX. Everything went fine until I tried to have my Sun computer send "SunView" to my MacX server. It didn't work. Instead of the client appearing on my screen, it showed the console screen. I tried the same thing with a VT100 terminal, and the same thing happened.

I know SunView is a "windowing" environment, but is it an X Window System? Isn't Sun's X Window System called OpenLook? Can SunView be a X client?

This article has been archived and is no longer updated by Apple.
SunView is Sun's older window system and is not an X client. Together, SunTools and SunView provide functionality similar to that provided by X Windows and X Windows-based applications -- that is, SunView provides a programming interface and basic windowing capabilities similar to X Windows. But this system is NOT X Windows, it is Sun's proprietary windowing environment, and is best thought of as a competitor to X Windows.

X is now the default window system shipping with new products (as of July 1990). Previously X was an unbundled product, available free from MIT or available from Sun for a media and documentation charge.

XNeWS is Sun's X server that interprets X protocol and PostScript (NeWS protocol). OpenLook is a functional specification for the "look and feel" of the user interface (by AT&T). X clients generally use X toolkits (like XView, XT+, OLIT, and so on), but they could simply make Xlib calls.

Thus, SunView is not an X Window System nor an X client; you can't display it on MacX. If the Sun machine has the Xlib and applications, you should be able to start one using a command similar to:

/usr/bin/xcalc -display mac:0,0

where "mac" is the Macintosh node name defined in the host's file.

Published Date: Feb 18, 2012

VAX: Need to Use Non-PostScript Printer

Is there software that lets the Macintosh print to a non-PostScript printer (for example, the LN03 or LA210 connected to a VAX via RS-232)?

This article has been archived and is no longer updated by Apple.
We don't know of a product that lets you do this. For non-PostScript printers connected to a VAX via RS-232, you normally have to save the file as text only, and send this file to the VAX queue, using the device name of the printer captured by that queue.

If you have DECnet support on the Macintosh, you can use the DECnet COPY command to copy the file to the VAX, using the VAX node name and printer device name as the destination (for example, ENGVAX::LPA0:, where "ENGVAX" is the DECnet node name of the VAX, and "LPA0:" is the printer name).

If you don't have DECnet on the Macintosh, you have to transfer the file to the VAX first, using a terminal emulation program and XModem or Kermit, and use a VAX/VMS DCL command to print the file.

A/UX 3.0 and X Installation Problems

Article Change History

01/15/93 - REVIEWED
* For technical accuracy.
01/15/93 - REVISED
* Updated article to A/UX 3.0.

Due to the size of the A/UX partitions, I decided to load X Window System in a separate partition. Modifying the path parameter in .profile and .login should provide the proper support for this location. It didn't work. It continued looking in the /usr/xxx/X11 directories versus /App/usr/xxx/X11 as was stated in the .profile command. What other supporting files need to be modified for this redirection? We accomplished the task via the link command "ln -s /xxx/xxx /xxx".

This article has been archived and is no longer updated by Apple.
The files X, X11, and X11R3 in the /usr/bin/X11 directory contain references to the /usr/bin/X11 and /usr/lib/X11 directories. There are several ways to get around this. You could add the environment variables $X11BINDIR and $X11LIBDIR to your .login or .profile files, setting them to the location of the new X lib and bin directories. If you are using the Bourne shell you would then export them, or if you're using the csh you would create them as environment variables (that is, with setenv(1)). You could also just link the new directories to the old locations, making symbolic links between the old and the new. Or you could modify the /usr/bin/X11/[X X11 X11R3] scripts to reflect the new directory locations. Any of these procedures should solve your problem.

Token Ring Cards: Incompatible with A/UX

Can I use TokenTalk NB Card under A/UX.

This article has been archived and is no longer updated by Apple.

You cannot run the Apple TokenTalk NB card or the Apple 4/16 Token Ring NB card under A/UX at this time.

AppleTalk Routers that Support TCP/IP

I want to install twenty Macintosh IIfx systems on an Ethernet. I don't want to connect my Macintosh IIfx directly to the Ethernet backbone. Now, I am looking for a router that can route Ethernet to Ethernet. Apple's Internet Router is no solution because I need TCP/IP routing.

Do you know of a TCP/IP and AppleTalk router (hardware or software) that can route between two Ethernets, not only LocalTalk to EtherTalk.

This article has been archived and is no longer updated by Apple.
There are a couple of alternatives. The NRC (Network Resources) router is a TCP/IP and AppleTalk combined router that runs on a Macintosh II class system. They also offer hardware based stand-alone routers that perform the same function. Cisco Systems and ACC (Advanced Computer Communications) both offer Ethernet-to-Ethernet routers that support both AppleTalk and TCP/IP.

Published Date: Feb 18, 2012

Parallel AppleTalk Internet Routers

What route does an AppleTalk message take if you have two AppleTalk Internet Routers connected in parallel? For example, if you have an EtherTalk backbone with two AppleTalk Internet Routers to a LocalTalk-based network, how and what decides which route the message takes?

This article has been archived and is no longer updated by Apple.
LocalTalk nodes use the router contained in the A-ROUTER variable. This variable is updated every time the node sees an RTMP packet. The source network number and node number of the RTMP packet are copied into the A-ROUTER variable. Sometimes, the packet travels to the EtherTalk backbone via the first router, and sometimes it travels to the EtherTalk backbone by the second router.

The best routing algorithm is implemented in EtherTalk 2.0, TokenTalk 2.0, and AppleTalk Phase 2 for A/UX and MS-DOS. It can, theoretically, be added to LocalTalk nodes at a later date.

In the past, a non-router node has not kept much information on how to get to other networks. A node kept track only of the address of one router on its local network, assuming that the router would know how to reach the rest of the Internet. Whenever the node had a packet to send to a different network, the node sent the packet to the one router it knew about.

Generally, this algorithm didn't cause any problems. However, in very large, bridged Ethernets or Token Rings, it can be inefficient, because the one router that a node knows about can be quite far away and not the best router to use.

With AppleTalk Phase 2, nodes can optionally keep information on how best to get to other networks. When a node that uses the best-routing algorithm gets a packet from another network, it looks at the address of the last router that forwarded the packet. This is the router it uses to get to that distant network in the future.

QuickTime for Windows: How to Determine Which Edition and Version Is Installed

This document explains how to determine which edition and version, such as Pro Player, of QuickTime is installed on a computer with Microsoft Windows installed.
This article has been archived and is no longer updated by Apple.
For Macintosh computers, see technical document 25220: "**QuickTime for Macintosh: How to Determine Which Edition and Version Is Installed**."

How to determine which edition is installed

1. Click the Start menu, choose Settings, then choose Control Panel (see Figure 1).

Figure 1 Opening the Control Panel window

2. Open the control panel named QuickTime (see Figure 2).

Figure 2 QuickTime control panel

3. Choose Registration from the pop-up menu (see Figure 3).

The field named QuickTime Key indicates which edition of QuickTime is installed. In Figure 3, QuickTime Pro is installed.

Figure 3 QuickTime Pro is installed

How to determine which version is installed

1. Click the Start menu, choose Settings, then choose Control Panel (see Figure 1).

Figure 1 Opening the Control Panel window

2. Open the control panel named QuickTime (see Figure 2).

Figure 2 QuickTime control panel

2. Choose About QuickTime from the pop-up menu. The version number appears below the pop-up menu. In Figure 4, QuickTime 5.0.2 is installed.

Figure 4 QuickTime Pro is installed

Upgrading to QuickTime Pro

For information on upgrading to QuickTime Pro, visit the QuickTime Web site (http://www.apple.com/quicktime/).

For information on the differences between QuickTime and QuickTime Pro, see technical document 24374: "**Differences Between QuickTime and QuickTime Pro**"

AppleTalk for VMS: Router Issues

I am having a problem with AppleTalk for VMS when connecting Macintoshes to other computer systems. If I use Liaison as a gateway between LocalTalk and Ethernet, I don't get any response from the AlisaTalk software on the VAX. I said that the RTMP table is not correct, so there is no connection between the networks. If I remove Liaison from the Macintosh and connect it directly to the Ethernet, there is no problem. I do not believe this is a problem with Liaison, because I have the same problem with Shiva FastPath.

Is this a known problem? Can you explain?
This article has been archived and is no longer updated by Apple.
There are two possible areas that might be causing the problems you are seeing.

The first has to do with AppleTalk Phase 2 versus AppleTalk Phase 1. It is possible that you have installed the Phase 2 version of AppleTalk for VMS without realizing it, and you are trying to use Phase 1 routers, like Liaison. There are two ways you can test this:

1) Open the ATKBRIDGE.LOG file on the VAX and check the version of AppleTalk for VMS that is being run. If it says you are running version 2.1, you are running the Phase 2 version of ATK/VMS.

2) On the machine you are running Liaison, run the Internet Router instead. If you run the Internet Router without the Phase 2 Upgrade Utility installed, and you can see the services, you are running AppleTalk Phase 2 on the VAX. If you cannot see the services, and then you install the Upgrade Utility along with Phase 1 EtherTalk on the router and you can see the services, you are running Phase 1. We also know that it is something about the other routers causing the problems.

The other area you should investigate if it is not a Phase 1 versus Phase 2 issue is network numbers. AppleTalk for VMS is a router. In the default configuration, it has specifications for two networks, the Ethernet the VAX is connected to and the virtual network running inside the VAX. When you add the other router to the network, you have to ensure:

1) AppleTalk for VMS and the new router have the same network number specified for the Ethernet.

2) The virtual network has a unique network number specified for it.

3) Any other networks connected to the new router have unique network numbers as well.

Each router has a different method for specifying network numbers. For AppleTalk for VMS, this information is maintained in the PORTDESC.TXT file in the AppleTalk directory.

A/UX 2.0: IBM "ftp" Problem

I am having problems with A/UX 2.0 and "ftp". When I do this:

Account Read

I get the message message:

230 Working directory is RVFC60 191 (read only)
Segmentation fault (core dump)

The network components are A/UX on an Ethernet connected to an IBM 8232 gateway through a Cisco Systems router to an IBM 3090 running IBM TCP/IP. The IBM operating system being used is VM/XA CMS. The CMS volume referenced in the error message has a proper READ password and is accessible using the same technique from a Sun Workstation.

The process worked once, but I'm not sure why. It has failed consistently ever since. Can you explain?

This article has been archived and is no longer updated by Apple.

We have duplicated the problem you describe, and it will be submitted as a bug report to A/UX Engineering. One workaround is to enter the "account" command by itself and then input the account information when "ftp" prompts you for it. This seems to prevent the core dump and lets "ftp" function normally. This problem is resolved in A/UX 3.0.

Published Date: Feb 18, 2012

A/UX 2.0: Various Issues

Can you help me with these A/UX 2.0 questions and problems?

1) "adb" does not seem to work. Therefore, I cannot debug my program. We have ordered MacsBug.

2) When using "sfgetfile" and "sfputfile," why is my home directory in "/"? It creates bad pathnames when I try to get something from

/usr/mgb/images/image1

The path I get from "sfgetfile" is

/mgb/images/image1

3) When I log in to A/UX after it says that it is starting "session for mgb", it clears the screen. Is this correct?

4) If I am "mgb" and I do a "df" disk free command, I get different values from when I am the "root". Try these next lines:

% df
xxx xxx xxx xxx
% su
# df
yyy yyy yyy yyy #

where x and y are different by about 10000 blocks.

This article has been archived and is no longer updated by Apple.

```
1) Use MacsBug version 6.2 or later.

2) The reason for this behavior is that under A/UX you have a virtual root that
  is accessible by all users (one at a time).  A/UX 2.0 puts your personal
  user directory onto the desktop so that you see it when you log in.  To do
  this, the Finder has "to play some games" with the UNIX file system to make
  this seem like what the Finder expects.  Folders on the desktop are at the
  root level under the Macintosh OS, so we had to try to emulate that behavior
  under A/UX.  This is why your path to your home directory appears as "/".
  It may be more proper from a UNIX standpoint to map the directory to its
  real location, but if you need that functionality use "open" or "fopen"
  instead of "sfgetfile".

3) No, that's not the correct behavior.  Check the contents of your .login
  file.

4) A/UX now uses the Berkeley file system.  As "root" you have no limitations
  on its use, as a normal user, there is a 10% overhead attached to each
  partition that is not available to a normal user.  This prevents unnecessary
  disk thrashing if the partitions become full.
```

A/UX: NFS Auto-Mount and other Support Issues (9/94)

1) What are secured RPCs, and does Apple support this in A/UX?

2) Does A/UX 3.0 have the NFS auto-mount feature? Also, what is auto-mount?

3) Does Apple support TCP/IP over Token Ring with A/UX?

This article has been archived and is no longer updated by Apple.
1) Secure RPC is an additional authentication flavor for ONC RPC that uses a public-key system to ensure that nobody is passing forged credentials over the wire.

The RPC protocol allows arbitrary authentication "flavors". Normally, the flavor "NULL" is used, or "UNIX", which carries around a UID and GID list, must be used from a reserved port to be trusted. The idea was that secure RPC would use DES encryption, based on keys obtained through a public-key distribution scheme.

Unfortunately, I don't know anyone who has successfully set up secure RPC (the primary application is, of course, secure NFS). There are also some ad-hoc changes done by Athena to use Kerberos authentication to NFS.

It differs from non-secure RPC in that it uses a different authentication flavor. ONC RPC supports multiple flavors of credentials:

AUTH_NONE - No credentials; the server has no idea who the user was who made the request, so there better not be any risks of an unauthorized user making the request.

AUTH_UNIX - UNIX user ID, group ID, and group list passed over the wire; if you work hard enough, and it's not *that* difficult, you can send somebody else's user ID over the wire--NFS servers often map user ID 0 to the user ID for "nobody", and may do other mappings, but few other servers do that kind of mapping.

AUTH_DES - "network name" passed over the wire, which is converted to the appropriate native machine credentials (for UNIX, a user ID, group ID, and group set) on the server. The credentials are encrypted using a public-key system, which makes it more difficult to forge credentials, but, allegedly, the public-key cryptosystem in question *is* breakable if you burn enough cycles.

"Secure RPC" in SunOS/ONC terms is RPC using AUTH_DES authentication.

Other flavors of authentication can be added by developers.

There is a very good writeup on Secure RPC in the "Security Features Guide" (part number: 800-1735-10), May 1988 for SunOS 4.0.x, section 6.3 "RPC Authentication." This information was moved to "Network and Communications Administration" (part number 800-3805-10), March 1990 in the SunOS 4.1 DocBox set, section 14.9 "RPC Authentication".

2) The auto-mount feature of NFS provides a mechanism to mount automatically NFS exported filesystems on the fly. This allows dynamic mounting of NFS partitions without having to explicitly mount the partitions from within the "/etc/fstab" file or by using the mount(1) command.

A/UX 2.0 does NOT have the NFS automount feature. However, A/UX 3.0 DOES have this feature.

3) There are no plans to support Token Ring under A/UX. Therefore, there are no plans to support TCP/IP running over Token Ring.

Zone Problems Caused by Old Phase 1 Routers

I have a Phase 1 network with FastPaths bridging between LocalTalk and Ethernet. It has a problem seeing a defined as 0, which is causing some network problems. What is the cause of this?

This article has been archived and is no longer updated by Apple.
The problem you're seeing is caused by older Phase 1 routers that are seeing the new-style, Phase 2 non-extended RTMP packets. New-style, non-extended RTMP packets have a special tuple as the first tuple in the set. This tuple contains 2 bytes of 0 and 1 byte used for an RTMP version number (0x82,131 decimal).

Older Phase 1 routers do not understand that this tuple is not a valid network tuple and, instead, interprets it as a distant network. This is usually reported as network 0, 131 hops away. This should not cause any significant problems for your network, but you should try to get all of your routers updated to the most recent releases available from the different vendors.

About the iPhoto Library folder

The iPhoto Library folder, located in your Pictures folder, contains photos you have transferred from your digital camera or other sources using iPhoto.
This article has been archived and is no longer updated by Apple.
About the iPhoto Library folder

Photos in the iPhoto Library folder are organized by the date they were taken. You can view all photos in your iPhoto Library folder from within iPhoto by clicking the Photo Library icon:

The iPhoto Library folder also contains any albums you create using iPhoto. Your photos aren't actually stored within each album; instead, the albums contain references to the photo files stored elsewhere in the iPhoto Library folder. This way, you can add the same photo to several different albums without actually duplicating the image file.

The iPhoto Library, as well as iPhoto CDs, contain a hierarchy similar to the one pictured in Figure 2. The hierarchy always begins with iPhoto Library, then contains a folder titled the year the picture was taken, followed by a folder for each month, and the day of the month under that. Finally, there are a number of files and folders. The Data folder contains data files that link photos to their thumbnails, which are located in the main date directory (09 pictured here) and in the Thumbs folder.

Important: Do not modify the contents of the iPhoto Library folder from outside the iPhoto application.

Use iPhoto to delete, duplicate, or modify any photos in the iPhoto library. Modifying the contents of the iPhoto library from anywhere but the iPhoto application could result in a library that is unusable and may cause photos and albums to no longer appear in iPhoto.

System 6.0.x, 7.x: How They Handle 4MB SIMMs

If a SIMM bank is filled with 4MB modules (giving 16MB), will 8MB be used by System Software 6.0.x, or will the system not know what to do with these SIMMs? We are concerned that these SIMMs will bomb the system.
This article has been archived and is no longer updated by Apple.
System software 6.0.x is a 24-bit operating system. When a Macintosh system is running system software 6.0.x, the Macintosh is in 24-bit mode. In 24-bit mode, the Macintosh II family of computers has the address space starting at $00 0000 through $7F FFFF (8MB) reserved for system RAM. The SIMM sockets use the entire system RAM address range of $00 0000 through $7F FFFF, which equals 8MB of RAM.

As you can see from this, with 24-bit addressing, installing four 4MB SIMMs would give you 8MB of usable RAM. The memory configuration under "About This Macintosh..." (About the Finder with System 6) will report 16MB installed, but 8MB is usable with the remainder being assigned to the system software. The extra memory assigned to the system software is unusable. In the case of the Macintosh LC, 2MB RAM is on the logic board. If you install two 4MB SIMMs, the Finder will report that 10MB of RAM installed. 8MB of RAM is usable.

With System 7, you have the option of turning on 32-bit addressing in 32-bit clean ROM computers, with the exception of the AV and Power Macintosh models which operate in 32-Bit mode at all times. (MODE32 installed on computers running System 7 versions prior to 7.1 or the 32-Bit System Enabler installed on computers running 7.1 will enable 32-bit operation). This allows addressing above 8MB in those computers that physically support more than 8MB of RAM.

A/UX is also a 32-bit operating system that can address above 8 megabytes of RAM. A/UX supports up to 256MB of physical RAM.

In 32-bit mode, the Macintosh II family of computers (which includes the Macintosh SE/30) has the address space starting at $0000 0000 through $3FFF FFFF (1 gigabyte) reserved for system RAM. NuBus RAM cards may use address $0000 0000 through $3FFF FFFF to add system RAM. The SIMM sockets use address $0000 0000 through $07FF FFFF, which equals 128MB of RAM.

Here's a list of the current Macintosh systems and the maximum physical memory that the SIMM sockets support:

Macintosh System	Maximum Physical RAM
Non 32-Bit clean systems	
Macintosh Plus	4MB

Requires the 32-Bit System Enabler with System 7.1 or MODE32 with versions of System 7 earlier than 7.1.

Requires the 32-Bit System Enabler with System 7.1 or MODE32 with versions of System 7 earlier than 7.1, as well as the FDHD upgrade kit and PMMU (The FDHD upgrade has been discontinued).

+ These models are designed to handle 16 megabyte SIMMs but only 4 megabyte SIMMs are officially supported by Apple at this time.

* There are two different reasons that the Macintosh II and the Macintosh IIx can't support the higher density SIMMs. First, the Macintosh II ROM startup code doesn't know about 4MB SIMMs and won't start up.

Second, the Macintosh IIx ROM does know about 4MB SIMMs, but standard 4MB SIMMs won't work on the Macintosh IIx. This is because JEDEC, the committee overseeing the standardization of new solid-state devices, added an additional built-in test mode to high-density DRAMs. The test mode is invoked by a sequence of electrical signals which was ignored by earlier-generation DRAM. This specification for 4MB SIMMs was changed after the Macintosh IIx was developed. At the time the Macintosh IIx was developed, in theory, 4MB SIMMs should have worked. It wasn't known at the time that the specification would be changed. The result is that the current standard 4MB SIMMs don't work on the Macintosh IIx.

There are special 4 Megabyte SIMMs available that have a PAL chip which will allow their use in the Macintosh II and IIx. You'll need to contact the SIMM vendor or manufacturer to see if they have these special SIMMs available.

This subject is described in detail in Tech Note #176.

The following Tech Info Library article can help you find the Tech Note mentioned here:

Macintosh IIfx: Serial Switch for Bypassing the IOP (6/97)

On the Macintosh IIfx, is there a way to disable or bypass the IOP (I/O Processor) that controls the SWIM and ADB, so that copy-protected programs that access the ADB hardware directly work properly?

I've been told that there is a cdev available that lets the user bypass the IOP for the SCC chip, enabling compatibility with serial devices that don't work with the IOP on the Macintosh IIfx. Is this true? If yes, where can I get this cdev?

This article has been archived and is no longer updated by Apple.

There is no way to bypass the IOP that controls the SWIM and ADB. The companies that sell the copy-protected programs need to modify their programs to work properly on the Macintosh IIfx.

It is possible to bypass the IOP that controls the serial ports. Attached is a control panel called "Serial Switch" that makes this possible. To bypass the IOP, just select "Compatible" in the Serial Switch control panel.

The cdev has two modes:

- Faster, when the IOP is used
- Compatible, enabling third-party developer's code to address the SCC hardware directly bypassing the IOP.

After choosing a different mode, you'll need to restart your system.

This software is available for individual use through online services that services that Apple post software updates to.

The CDEV is also available from Software Licensing for those developers who want to distribute it with their products. The yearly fee is $50 per product it is to be distributed with. No limit is set on the number of copies that can be distributed by a developer. For more information, search for "Apple Software Licensing" or call 408-974-1010.

Softcard III: Diskette compatibility with Apple II CP/M

This article has been archived and is no longer updated by Apple.
The diskette organization used in the Apple II Softcard CP/M and the Apple III Softcard CP/M are identical. This means that files generated on either system is readable by the other. However, the Softcard III CP/M System File does not work correctly on an Apple II, and visa-versa.

Some programs were designed with specific hardware in mind and may not work correctly on the Apple III. Several examples are MBASIC, GBASIC, and FORTRAN supplied by Microsoft.

Macintosh: How System Heap Size Is Allocated (11/94)

1) Where is the heap size stored on a volume?

2) If I adjust a heap size on a volume and copy that System Folder to another empty drive, will the boot blocks be set to the new modified size?

This article has been archived and is no longer updated by Apple.
The default heap size is stored in the boot blocks of a startup volume. For System Software 6.0.4 and System Software 6.0.5, the default size 128K.

Note: When the System Software 6.0.5 System Tools disk is booted on a Macintosh SE with 1MB RAM, the System heap takes up 188K of RAM. The default System heap size is used as a guideline; the heap size is increased, if necessary.

The boot blocks, including the default heap size, are taken from the source disk, unless that disk does not have a valid copy of the boot blocks or if it is a file server. In these cases, the boot blocks are taken from the "boot" resource in the System file being copied.

Caring for iPod‘s battery

Here are some tips to care for iPod's internal battery.
This article has been archived and is no longer updated by Apple.

- Keep iPod comfy:
  - Operating temperature range: 32 ° F to 95 ° F (0 ° C to 35 ° C)
  - Storage temperature range: -4 ° F to 113 ° F (-20 ° C to 45 ° C)
- Do not leave iPod in a vehicle's interior when parked in the sun. Temperatures may reach up to 150 ° F (65 °C).
- Do not leave iPod exposed to direct sunlight for extended periods of time.
- Do not charge iPod while it is in a carrying case or cover.
- Put iPod to sleep to save battery life. Press the Play button until iPod goes to sleep.
- Charge the battery every 14 to 18 days when not in use. Even when iPod is off it is in a sleeping state that requires power. Without use, iPod's battery needs to be charged about every 14 to 18 days to be ready for use.
- If iPod displays a "Low Battery" icon, connect it to the Apple iPod Power Adapter and plug the power adapter into an electrical outlet. You may also be able to charge iPod by connecting it to your computer. Make sure the computer is turned on, and is not set to go to sleep.

For more information about charging iPod's battery, see article 61127: Charging iPod's internal battery.

Softcard III: Accessing Apple III system clock under CP/M

This article has been archived and is no longer updated by Apple.

The Apple III clock is accessible from machine language under CP/M. There are two call addresses in BIOS used to read and set the clock. Both use a common 18 byte area for returning the Date/Time or for setting the clock. If no clock is installed, the byte at 0DFE0H is 00H.

To Set Clock: Call 0DF89H

To Read Clock: Call 0DF86H

Example: Friday, March 21, 1982, 1:27 PM and 41.234 seconds is represented as the ASCII string: "1982032161327412 34".

Addresses Contents
Hex ASCII
Year: 0DFE0H 31 (1)
0DFE1H 39 (9)
0DFE2H 38 (8)
0DFE3H 32 (2)

AppleShare PC: 3.5-Inch and 5.25-Inch Install Disks

My office does not have a dual 5.25-inch drive PC. This makes it cumbersome to copy AFE the files, because when I find that they are the wrong ones, and have to go back to AFE. What files does install.exe look for when doing the four different installs (printing, printing, file access, and so on)?

This article has been archived and is no longer updated by Apple.
AppleShare PC 2.0 shipped with both a 3.5-inch 720K install disk, and a set of 5.25-inch 360K install disks. The files contained on the 5.25-inch disks are no different than those on the 3.5-inch disk; they're just divided across two disks. However, as you have found, the distribution of the files is important.

Until you get the new version, you can make a functional set by creating two disks with the file distribution listed below. After you copy all the files, Disk #1 will have approximately 4K available, and disk #2 will have approximately 33K available. Neither has enough space for MS-DOS system files.

Internet Explorer 4.5: "The Identity Certificate Uses an Unknown Signature Algorithm" Alert

Update your version of Internet Explorer to avoid an alert box with the message "The identity certificate uses an unknown signature algorithm."
This article has been archived and is no longer updated by Apple.

Symptom

When you browse a secure Web site an alert box with this message appears:

> "The identity certificate uses an unknown signature algorithm."

Solution

All versions of Internet Explorer later than 4.5.1, including all Mac OS X versions, are not affected by this issue.

iMovie 2 for Mac OS 9: Aurora Igniter INIT Causes Clips to Move to the Trash

The Aurora Igniter INIT system extension causes imported clips in iMovie to be moved to the Trash .
This article has been archived and is no longer updated by Apple.

Symptom

When the Aurora Igniter INIT system extension is installed, clips imported into iMovie 2 for Mac OS 9 are placed directly in iMovie's Trash rather than the shelf.

Solution

Use the Extensions Manager control panel to turn off the Aurora Igniter INIT.

1. Open the Extensions Manager control panel.
2. Turn off the Aurora Igniter INIT by clicking the checkbox next to its name.
3. Restart the computer.

If you need the Aurora Igniter INIT to be enabled for other applications, turn it on using the Extensions Manager control panel, then restart the computer.

iMovie 2 for Mac OS X: Unable to Import Some JPEG and GIF Images

JPEG and GIF files without file types cannot be imported into iMovie for Mac OS X. Some images may be available in the Import dialog, some are dimmed. These images can be opened in other applications, like Preview.
This article has been archived and is no longer updated by Apple.

Symptom

Some JPEG and GIF files cannot be imported into iMovie. Some images are available in the Import dialog, some are dimmed. iMovie 2 for Mac OS 9 can import the images.

Solution

If Preview can open the files, you can use Preview to export the images for use with iMovie. Follow these steps:

1. Open the Preview application.
2. Choose open from the File menu.
3. Select and image and click Open.
4. Choose Export from the File menu.
5. Choose JPEG or PICT from the Format pop-up menu.
6. Choose a destination folder.
7. Click Save.
8. Import the images into iMovie.

You can also use a third-party utility to manually add file type/creator codes to the affected file(s).

German iTunes 2.0.3 for Mac OS 9: Installation Fails

Installing German iTunes 2.0.3 for Mac OS 9 fails with an unexpected End Of File error.
This article has been archived and is no longer updated by Apple.

Symptom

If you install German iTunes 2.0.3 on a computer with German Mac OS 9, when an earlier version of iTunes version was installed, an alert box with this message appears: "End of File," and the installation fails.

Solution

1. Drag the iTunes application to the Trash. (You do not need to delete the Plug-ins folder.)
2. Choose Empty Trash from the Special menu.
3. Install iTunes 2.0.3.

The iTunes application and all Apple-supplied plug-ins are installed.

HyperCard 2.0: New Product Features (2 of 2)

This article has been archived and is no longer updated by Apple.

HyperTalk Enhancements

- The Script Editor supports numerous of new features:

- Modeless windows (several open at same time)
- Search and Replace
- Commenting and uncommenting selected lines
- Undo for cut, copy, paste, clear, and typing operations
- Horizontal scrolling (for 2-page display)
- Triple-clicking to select a line
- Allows setting of debugging checkpoints

- The HyperTalk Compiler replaces the HyperTalk interpreter used in earlier versions. As a result, HyperTalk scripts run faster in HyperCard 2.0 (as much as three times faster). Handers are compiled automatically on the first execution of the handler and the compiled code is cached in RAM to be available for subsequent calls to that handler. The compiled handler remains in memory until that memory is needed for other handlers. When HyperCard 2.0 quits, the compiled HyperTalk code is flushed from memory, so only the HyperTalk source code is saved to disk.

- The HyperTalk Debugger engages when a execution encounters checkpoint. These checkpoints are inserted in the source code using the script editor. You can also enter the debugger by pressing Command-Option-Period.

- Background Processing: With HyperCard 2.0, you can switch to another application under MultiFinder while a script is running, and the script will continue to execute while HyperCard 2.0 is in the background. Other functions, like sorting and compacting also work while HyperCard 2.0 is in the background. HyperCard 2.0 yields to MultiFinder at the following times:

- At the completion of a HyperTalk line.
- When the busy cursor rotates (sorting, compacting, and printing)
- During the execution of the Show Cards and Wait commands

HyperCard 2.0 notifies the user whenever user intervention is required.

- XCMD Enhancements: The XCMD interface in HyperCard 2.0 is an extension of the XCMD interface originally implemented in HyperCard. HyperCard 2.0 provides the means for XCMDs to create and manage their own windows and menus and to call the sound manager directly. HyperCard 2.0 uses this XCMD window interface to implement the Script Editor and Debugger.

- Color Windows: While the card window does not support color, an XCMD can own a color window that supports bit depths of up to 24-bits. This lets the stack creator display a color picture while inside of HyperCard.

- Sound Control: Now, XCMDs can call the sound manager directly for increased control over sound from an XCMD.

Miscellaneous. Enhancements

- Custom Menus: The entire menu bar and its contents can be controlled by a HyperTalk script. This lets stack creators add, modify, or remove any menu items. As a result, you can make stacks that look like stand-alone applications, without having to resort to XCMDs.

- Palettes: HyperCard 2.0 has a feature which lets users create palettes,

similar-to the Tools palette and the Patterns palette. To create these palettes, you must create a PICT resource that defines the visual part of the palette. This can be created in many of the popular paint programs and can be in color. You must also create a PLTE resource to define the rectangles for the buttons in the palette and the HyperTalk scripts that are executed when each is pressed. Creating a palette does not require coding in languages like Pascal, C or Assembly.

- Icon Editor: HyperCard 2.0 has a built-in icon editor, so that you can create or modify icons without the use of utilities such as ResEdit.

The editor displays a "fat-bits" representation of the icon, in which you can click within the image to toggle bits on or off. There are also several menu commands that further help you edit icons. They include the commands Flip Horizontal, Flip Vertical, Frame, Gray, Invert, Mirror Horizontal, Mirror Vertical, Rotate 90 degrees, Shadow, and Pickup.

- Marked Cards: Now, each card has a Mark property that lets a user or HyperTalk handler flag a card for some reason. Usually, this feature is used by a HyperTalk script during a search for cards that contain information that matches a certain criteria. Each card that contains that information is then marked. Once the appropriate cards have been marked, they can be processed as needed.

This feature is used with the HyperCard 2.0's report-printing capabilities to select which cards will be included within a report. For example, in a quiz the developer could mark the cards the student got wrong and print those cards out for later review.

- Visual Effects: In the past, visual effects have only worked on monitors set to 1 bit per pixel. HyperCard 2.0 supports visual effects on monitors set up to 8 bits per pixel. There are two new visual effects--Stretch and Shrink.,

To help make it easier for stack developers to use visual effects, HyperCard 2.0 has a visual effects selection dialog for buttons. This dialog is illustrated below.

- Dynamic Dialog Sizing: Most of the HyperCard 2.0 dialogs, including the Ask and Answer dialogs, can now hold more text and size themselves to fit the amount of text. The previous limit was one line of text. This limit has been raised to approximately 240 characters, and as many lines that can be displayed on a classic, nine-inch Macintosh screen. For example, if a stack pathname is too long to fit on a single line, the Stack Info dialog will resize itself to fit up to five lines to accommodate the pathname.

- Painting Enhancements: New special effects have been added to HyperCard 2.0's Options menu.These effects work on graphical selections chosen with HyperCard 2.0's paint Selection tool. The four new effects are:

- Rotate to provides free rotation of graphics about the center of the selection.

- Slant to stretch the selection into the shape of a parallelogram, making the image appear slanted.

- Distort to let you stretch a corner of the selection arbitrarily in two directions

- Perspective to stretch the selection into the shape of a parallelogram or trapezoid, making the image appear to have perspective depth.

- Stack Security: When protecting stacks, HyperCard 2.0 has the two new possibilities of Can't Peek and Can't Abort. Can't Peek lets stack developers protect confidential script source code from users. Can't Abort

prevents users from pressing Command-Period to stop execution of a HyperTalk handler. When this protection is set, execution of handlers cannot be prematurely halted by the user.

Note: Both of these features should be used with care. In most cases, it is advisable to lock only copies of the stack, and not the original stack.

Saving contact information from Address Book to iPod‘s Contacts list

The easiest way to save contact information to your iPod is to use iSync. You can also use the Mac OS X Address Book application to save contact information as a vCard on your iPod.
This article has been archived and is no longer updated by Apple.

1. Make sure iPod is set up to be used as a hard disk you can store files on.
2. Connect iPod to your computer. iPod appears as a hard disk on your desktop or in a Finder window.
3. Double-click the iPod disk icon.
4. Open the folder named "Contacts".
5. Open the Address Book application program.
6. Drag the names of contacts from Address Book to the Contacts folder.

iPod can work with up to 1000 contacts.

NEC DM-3000P Monitor: Connecting to a Macintosh

What are the specifications for the cable to connect a Macintosh to an NEC IPS-100 Monitor?

This article has been archived and is no longer updated by Apple.

According to NEC technical support, the most efficient way to connect the Macintosh (with the older Apple 8-bit video card) is to use a cable from Inline, Inc. (part number is IN9021). This connects the 15-pin connector on the older Apple 8-bit video card to the 34-pin connector on the DM-3000P.

At this writing, NEC had not tested this cable with the newer Apple video cards, but it may work unless there is a problem with the configuration of the sense pin connections on the new cards. The sense pins are used to let the new video cards know what mode to use.

Inline checked the configuration information and said that there is no need for the NEC IPS-100 Computer Interface when connecting the DM-3000P to the Macintosh. Their IN9021 cable, which is 15-pin-to-34-pin, is all that is needed to connect the two.

For further information on Inline, search the Tech Info Library using "Inline, Inc."

Macintosh: How to Connect to UPI News Service

Can I connect to the UPI wire service from a Macintosh?
This article has been archived and is no longer updated by Apple.
According to UPI (United Press International), all you need is a:

* Modem
* Communications program
* Subscription to the UPI service

News services like UPI are aimed at media clients: newspapers, magazines, radio, and television. Direct connections to these services are more expensive than the average individual can afford. For those interested in news services, an alternative is to use commercial network services like CompuServe or GEnie. These are far less expensive, but contain a wide range of information.

Macintosh 12" RGB Display: Software Compatibility

This article has been archived and is no longer updated by Apple.

Several applications do not recognize the Apple Macintosh 12" RGB Display as being 512 x 384 pixels instead of 640 x 480. This leads to windows that are partially off the screen. ColorStudio 1.0 and PixelPaint 2.0 are two applications with this problem. In some cases, the windows can be resized -- but in others, there is no way to work with the application and restarting the system is the only way out.

Softcard III: Selecting 40-Column and 80-Column Text Modes

This article has been archived and is no longer updated by Apple.
There are several ways to switch to either 40 or 80 column mode in the CP/M environment. One way is to write a short assembly language program, assemble it, then load it as a .COM file. Another way is to use the BASIC's CHR$ functions to change modes. Don't forget to reset the viewport when changing to 80 column mode. Refer to the Standard Device Drivers Manual for further information.

Below are two assembly language programs which allows you to set 40 or 80 column modes from the CP/M command level. Enter these in your ED.COM editor, then assembled them using ASM.COM. Once assembled, load them into .COM files using the Load utility on the CP/M System Disk.

```
;
; Forty.COM
;
BDOS EQU 0005H ; BDOS entry point
WARM EQU 0000H ; Warm start entry point
PRINT EQU 9 ; Print string command
;
ORG 0100H ; Beginning of TPA
;
LXI D,CMDS ; Point to command string
MVI C,PRINT ; Set-up BDOS command
CALL BDOS ; Call BDOS to print string
JMP WARM ; Warm start return to CP/M
;
CMDS: DB 16 ; Set text mode
DB 1 ; To 40 column mode
DB 28 ; Clear viewport command
DB '$' ; End print string command
;
End
```

```
;
; Eighty.COM
;
BDOS EQU 0005H ; BDOS entry point
WARM EQU 0000H ; Warm start entry point
PRINT EQU 9 ; Print string command
;
ORG 0100H ; Beginning of TPA
;
LXI D,CMDS ; Point to command string
MVI C,PRINT ; Set-up BDOS command
CALL BDOS ; Call BDOS to print string
JMP WARM ; Warm start return to CP/M
;
CMDS: DB 16 ; Set text mode
DB 2 ; To 80 column mode
DB 1 ; Reset viewport
DB 28 ; Clear viewport command
DB '$' ; End print string command
;
End
```

From Microsoft BASIC, use:

A. To switch to 40 Column mode:

```
100 Print CHR$(16) + CHR$(1) + CHR$(28)
110 End
```

B. To switch to 80 Column mode:

```
100 Print CHR$(16) + CHR$(2) + CHR$(1) + CHR$(28)
110 End
```

Mac OS X: Application Opens But Doesn‘t Use Classic

Symptom

An application or installer opens, but doesn't use Classic. The application's plug-ins don't work without Classic.

Products affected

- Mac OS X

Solution

Some applications are made to work with both Mac OS 9 and Mac OS X. If you double-click one of these applications while using Mac OS X, it will open as a Mac OS X application without starting Classic.

However, some Classic applications have plug-ins and other resources that are only available if you use them with Classic. Some installer applications, for example some third-party printer driver installers, will automatically detect whether they are opened in Mac OS 9 or Mac OS X and only install the components appropriate to that operating system.

To avoid this issue, you can have the application or installer always open using Classic.

Select the application or installer and choose Show Info (Mac OS X 10.1 or earlier) or Get Info (Mac OS X 10.2 or later) from the File menu, then select the checkbox to have the application open using Classic.

Note: If the installer application is located on a read-only volume, such as an installation CD, it, and any files it needs for installation, must be copied to a read-write volume first. If you cannot install in this way, contact the manufacturer of the software for compatibility information and further assistance.

Macintosh IIsi: Application Software Compatibility

This article summarizes the software compatibility issues at the introduction of the Macintosh IIsi.

This article has been archived and is no longer updated by Apple.

The Macintosh IIsi Was Widely Seeded

In the United States alone, over 300 developers received Macintosh IIsi seed units. Many other developers received full documentation, and were able to test their products at Apple. This was the most extensive seeding and testing of a new computer in recent history.

Of the applications on which Apple had compatibility information, 97% either worked with the Macintosh IIsi, or were in the process of being revised. The other 3% were discontinued products.

Compatibility Issues

FPU: Apple identified about twenty application programs that required an FPU (and did not have an alternate non-FPU version). Many of the color paint programs that fell in this category were revised to work on all Macintosh models. However, most CAD/CAM programs and other high-end graphics/math programs still require an FPU. We will identify these applications on all compatibility lists.

Microsoft Excel: Version 2.2a or higher is recommended for all Macintosh IIsi and Macintosh LC configurations. Microsoft offers a free upgrade from 2.2 to 2.2a.

Monitor size: Several programs did not work properly on the Apple Macintosh 12-inch RGB Display, because they assumed a minimum 640-pixel by 480-pixel size. These programs were in the process of being revised.

Macintosh SE/30 cards: Some Macintosh SE/30 cards did not work with the Macintosh IIsi, due to incorrect timing and physical dimensions. All cards that followed the guidelines in Apple's "Cards and Drivers" manual work correctly.

NuBus power requirements: Some NuBus cards exceeded the 15W power maximum specification. These cards were primarily the high-end graphics and video cards. We asked developers of these cards to include, in their manuals, references to power if they exceeded the maximum specification. We also included a caution in the Macintosh IIsi manual.

Sound: The new sound input software made it necessary for some developers to update their software. Latest versions should work with the new Macintosh models.

AppleTalk: An AppleTalk problem in System 6.0.6 was fixed in System 6.0.7, which shipped with all Macintosh IIsi and Macintosh LC systems sold in the United states.

Published Date: Feb 18, 2012

Macintosh IIsi: Compatibility With Selected Software 1/93

Apple recommends that customers use the latest versions of Macintosh software that are compatible with their Macintosh hardware. Apple compiled the following list from information received from many software developers. These developers have recommended certain versions of their software for use with the Macintosh IIsi computer.

This article has been archived and is no longer updated by Apple.

This is not a comprehensive list of programs, or versions of programs, that are compatible with the Macintosh IIsi. Please contact your dealer or the software developer if you have any questions. They can help you identify the newest version of a particular program and tell you how to upgrade if necessary.

Macintosh IIsi: Expansion Card Compatibility

This article describes some of the compatibility issues between the Macintosh IIsi and NuBus and 030 direct cards. To determine if a given card has any of the following problems with the IIsi, the manufacturer of the card should be contacted.

This article has been archived and is no longer updated by Apple.

CARD POWER REQUIREMENTS

Some NuBus cards exceed the 15-watt limit for NuBus cards. In the case of Macintosh II models with multiple NuBus slots, an empty NuBus slot usually provides some margin. Because the Macintosh IIsi is a one-slot system, that margin does not exist. As a result, it is more critical that the 15-watt power requirement for NuBus cards be maintained in the Macintosh IIsi.

For example, the Apple Macintosh Display Card 8*24 GC takes slightly more power, due to the processor and on-board memory, than the NuBus power specification of 15 watts. However, after the completion of initial tests, Apple is able to recommend using the card with the Macintosh IIsi in normal operating environments. Apple is continuing testing for elevated temperature environments. We will publish results of these tests as they become available. Until then, we do not recommend the combination of Macintosh IIsi and Macintosh Display Card 8*24 GC in environments where the temperature is expected to regularly exceed 32 C or 90 F.

For more information on Macintosh Display Card 8*24 GC, search under "Macintosh IIsi" and "Display Card 8*24 GC".

With regard to third-party cards, we have found the vast majority to be completely compatible and to work reliably with the Macintosh IIsi. In those few instances where the power specification exceeds the NuBus specification, or if you have any questions or concerns about a specific product, contact the vendor. In Apple's case, we can now recommend all of our displays cards across the line of NuBus-capable Macintoshes.

CARD SIZE

NuBus and 030 Direct cards that deviate from the size specifications of each type of card may experience fit problems. Also, NuBus cards that are a two-card set, such as a video card and an accelerator, will not work in the Macintosh IIsi.

CLOCK SIGNAL

Macintosh SE/30 cards that depend on the 16-MHz clock speed of the Macintosh SE/30 do not work with the Macintosh IIsi because the clock speed of the Macintosh IIsi is 20 MHz.

Mac OS 8.6: JPEG Pictures and Movies Appear Blank With QuickTime 5.0.5

On certain computers with Mac OS 8.6, pictures or motion JPEG files may appear blank when QuickTime 5.0.5 is installed.
This article has been archived and is no longer updated by Apple.

Symptom

JPEG pictures or motion JPEG files appear blank or have poor playback.

Solution

Delete the QuickTime JPEG Update file from the Extensions folder by following these steps:

1. Open the System Folder.
2. Open the Extensions folder.
3. Open the QuickTime Extensions folder.
4. Drag the QuickTime JPEG Update file to the Trash.
5. Choose Empty Trash from the Special menu.

iMovie 2.1.1 for Mac OS X: Scrambled Thumbnail Images in the Timeline

In some situations, thumbnail images for clips may become garbled or scrambled. This can happen after performing a Split Clip function, followed by an Undo and then a Redo action.
This article has been archived and is no longer updated by Apple.

Symptom

Thumbnail images for clips may appear garbled or scrambled.

Solution

The thumbnail is a visual representation of the media contained in your clips. The symptom described above is cosmetic, and does not affect your video content. Apple is investigating possible solutions for this. If you
split the clip again, the first clip will keep the scrambled thumbnail, while the second clip generates a new thumbnail.

To work around this behavior while keeping the same clip length, you can apply an effect such as Brightness/Contrast, with flat settings, so the clip and its thumbnail are re-rendered.

1. Select an affected clip in the Timeline. (See Figure 1.)

Figure 1 An affected clip

2. Click Effects.
3. Choose an effect like Brightness/Contrast or Adjust Colors.
4. Choose a setting which most closely matches your current image. (See Figure 2.)

Figure 2 Selecting an effect

5. Click Apply. The clip and thumbnail will be rendered again. (See Figure 3.)

Figure 3 A re-rendered clip

Published Date: Feb 18, 2012

Final Cut Pro 3: AE Plug-in Performance With External Video

Certain third-party After Effects plug-ins can take longer than normal to update in Final Cut Pro each time a settings change is made to them in the Viewer if a video monitor is connected through FireWire. Because filters in Final Cut Pro must render for both the RGB screen as well as for the video out signal, you can eliminate this delay by setting External Video to Off (Command-F12).

This article has been archived and is no longer updated by Apple.

Symptom

The watch cursor appears for a long period every time a setting is changed in a third-party After Effects plug-in.

Products Affected

- Final Cut Pro 3 for Mac OS 9 or Mac OS X

Solution

Set External Video to Off (Command-F12)

Published Date: Feb 18, 2012

LaserWriter: Password Reset (12/94)

A "Trojan horse" program has been circulating that sets the password of PostScript LaserWriters to a value other than the default "0" -- preventing printing with Apple's driver. It does not duplicate itself like a virus, and is not widespread, but can be embedded in any PostScript code being sent to a LaserWriter.

This article has been archived and is no longer updated by Apple.
The symptoms of the trojan horse include the printer's name appearing in the Chooser dialog box, but when someone tries to print, the error message "Invalid Access" may appear. If the Print Monitor is in use, the error message "Job cannot be printed, but the document is OK" may appear.

Apple is providing a utility program that resets the password of PostScript LaserWriters to the default "0". This allows users to again access the printer. If a customer experiences the above symptoms, use this utility before deciding to replace the LaserWriter's controller board.

This utility only works on the LaserWriter, LaserWriter Plus, LaserWriter IINT, LaserWriter IINTX(J) and the Personal LaserWriter NT printers.

The binary attachment mentioned in this article is enclosed and available only in the AppleLink version of the article.

Article Change History:
01 Dec 1994 - Combined similar article with this one.
30 Sep 1994 - Reviewed for technical accuracy.
02 Feb 1993 - Updated to explain how to locate the binary attachment.

DVD Studio Pro: About Defining a Startup Action

This document describes the Startup Action property, and why you may want to set this property.
This article has been archived and is no longer updated by Apple.
When authoring a DVD-Video disc using DVD Studio Pro, you have the option to choose the "startup action". This is the function that tells the disc what to do when it's inserted into a DVD player. For example, you might set your startup action to go directly to a main menu, or to display a copyright warning screen.

It's generally wise to set the startup action property when authoring a disc. While the DVD specification allows for a startup action to be undefined, a disc without the startup action property defined requires some action by the user. Most users expect to be presented with a menu or some information when they put a DVD-Video disc into their player. Also, some players may not play discs that don't have a startup action defined.

The Startup Action property is located under the General section of the Property Inspector. For more information, consult the DVD Studio Pro manual.

iPod: Screen Is Dark After Charging in a Carrying Case

iPod's screen may become temporarily dark if you charge it in a carrying case.
This article has been archived and is no longer updated by Apple.

Symptom

The screen becomes temporarily dark if you charge iPod while it is in a carrying case.

Solution

You should not charge iPod while it is in a carrying case. Remove iPod from any case before charging it.

Published Date: Feb 18, 2012

iTunes: How to Overcome 32 000 Song Library Size Limitation

iTunes 2 music libraries are limited to 32 000 songs. You can overcome this limitation by creating multiple libraries.
This article has been archived and is no longer updated by Apple.
Note: iTunes 4 no longer has this limitation. See <**http://www.apple.com/itunes/**> for information on updating to iTunes 4.

A single iTunes 2 music library can hold 32 000 songs. To accommodate more songs, you can create additional music libraries. Follow these steps;

1. Locate the "iTunes Music Library (2)" file inside the iTunes folder (in Documents).
2. Create a folder called "Backup" and copy the iTunes Music Library (2) file to it. If you make a mistake or change your mind about creating multiple Music Library files, you can go back to using this backup file.
3. Create a folder called "Library 1" and copy the iTunes Music Library (2) file to it.
4. Create a folder called "Library 2" and copy the iTunes Music Library (2) file to it.
5. Repeat for each increment of 32 000 songs. For example, if you have more than 64 000 songs, make two Library folders, if you have more than 96 000 songs, make three Library folders, and so forth.
6. Open iTunes, add, delete, or change the songs in the Music Library for the first 32 000 songs.
7. Quit iTunes, copy "iTunes Music Library (2)" mentioned in step 1 into Library 1.
8. Open iTunes, add, delete, or change the songs in the Music Library for the next 32 000 songs.
9. Quit iTunes, copy "iTunes Music Library (2)" mentioned in step 1 into Library 2.
10. Repeat for each 32 000 increment of unique songs

To access each of the different Music Libraries, copy the respective "iTunes Music Library (2)" file to the iTunes folder (in Documents), replacing the "iTunes Music Library (2)" file that is there. **Important:** If you accidentally move the file instead of copying it, make sure you move it back to the respective folder, or else you may have to redo some of the setup steps.

iDVD 2: Unexpectedly Quits When Opening Tutorial

You may not be able to open the iDVD tutorial if you are not a Mac OS X Admin user.
This article has been archived and is no longer updated by Apple.

Symptom

iDVD unexpectedly quits when you open the iDVD tutorial.

Solution

Follow these steps to alter the iDVD tutorial so that it may be opened by non-Admin users:

1. Log in as an Admin user.
2. Open the iDVD 2 folder.
3. Press the Option key while dragging the Tutorial folder to the Desktop. A copy of the Tutorial folder is made on the desktop.
4. Rename the original Tutorial folder in the iDVD folder to "Tutorial (original)".
5. Select the new Tutorial folder on the desktop.
6. Choose Show Info from the File menu. A new window appears.
7. Choose Privileges from the pop-up menu.
8. Choose Read & Write from the Everyone pop-up menu.
9. Click Apply.
10. Drag the new Tutorial folder from the Desktop into the iDVD 2 folder.

Non-Admin users should now be able to open the iDVD tutorial.

Macintosh: Which Models Provide SCSI Termination Power

On Macintosh systems with third-party internal SCSI hard drive, does the drive need to provide termination power, or does the Macintosh supply this power?

This article has been archived and is no longer updated by Apple.

The Macintosh Plus, Macintosh Portable, and some Macintosh PowerBook computers do not provide SCSI termination power. All other Macintosh computers with SCSI drives provide internal termination power. Macintosh computers which utilize an IDE-style hard drive do not supply termination power.

These PowerBook computers supply termination power

- PowerBook 2400
- PowerBook 3400
- PowerBook G3
- PowerBook G3 series
- PowerBook Duo series

These PowerBook computers do not supply termination power

- PowerBook 100 series
- PowerBook 500 series
- PowerBook 1400

Final Cut Pro 3: Orange Viewer/Canvas Windows

Final Cut Pro will display an orange frame in the Viewer or Canvas window to indicate that video cannot be played in the current configuration. Reasons you may see the orange frame include low video memory, low system memory, or using incompatible video cards.
This article has been archived and is no longer updated by Apple.

Symptom

In either the Viewer or Canvas, an orange frame is displayed instead of the expected video. Audio plays normally.

Solution

Try one or more of the following:

- Make sure you are using a video card that works with RAVE
- Lower the display resolution
- Lower the display color bit depth
- Disconnect a second monitor if one is connected
- Resize the Canvas window to no more than 100 percent

iPod: About Software Update

This document explains how the iPod Software Updater works when you download it from the Software Update pane of System Preferences (Mac OS X), or the Software Update control panel (Mac OS 9).
This article has been archived and is no longer updated by Apple.
You can download iPod Software Updater from Apple Software Downloads, the iPod download page, or you download it using the Software the Software Update pane of System Preferences (Mac OS X), or the Software Update control panel (Mac OS 9).

iPod Software Updater will appear in the Mac OS Software Update feature whether you have an iPod or not. If you don't have an iPod and want to make the update inactive so it won't appear, follow the steps in "Mac OS X: How to Make a Software Update Inactive or Active".

If you have an iPod, you can download the iPod Software Updater by following these steps:

1. Open Software Update.
2. Click Update Now. The iPod Software Updater appears in the list of available updates.
3. Click the checkbox in the Install column.
4. Click Install. The update is downloaded into the iPod Software Updater folder, inside of the Utilities folder, inside the Applications folder in Mac OS X, or inside the Applications (Mac OS 9) folder in Mac OS 9. If you have moved or renamed the Utilities folder in Mac OS X, a new Utilities folder will be created inside the Applications folder. The Software Update installation will then proceed in this new folder. If you have moved or renamed the Utilities folder in Mac OS 9, the Software Update installation will not work. In this case, you should download the update from Apple Software Downloads.
5. Connect iPod to your computer using the included cable.
6. Open iTunes.
7. iTunes will check the Utilities folder for the update, compare the versions of iPod software, and offer to install the later update.
8. Click OK. iTunes installs the update.

Final Cut Pro: Updaters Require Original Application Name

Updaters for Final Cut Pro will not install correctly if the application name has been modified. For example, if the program name has been changed from "Final Cut Pro" to "Final Cut Pro 3.0.1".
This article has been archived and is no longer updated by Apple.

Symptom

- When you try to install and update, an alert box appears with a message that says no software could be found.

or

- The installer appears to work, but the installation is incomplete.

Solution

Change the name of the application back to "Final Cut Pro" and run the installer again.

Mac OS X 10.1, QuickTime 5: Third-Party Components Do Not Install

Third-party components of QuickTime 5 do not install if the user's preferred language is Brazilian Portuguese, or Danish.
This article has been archived and is no longer updated by Apple.

Symptom

Third-party components of QuickTime 5 do not install if the user's preferred language is Brazilian Portuguese, or Danish.

Solution

As a workaround, users familiar with English may install the components by following these steps:

1. Open System Preferences.
2. Click International.
3. Click the Language tab (if necessary) and drag English to the top of the list.
4. Choose Log out from the Apple menu.
5. Log in.
6. Connect to the Internet.
7. Open the QuickTime Player application.
8. Choose Update Existing Software from the QuickTime Player application menu. The software updates will now install.

When you've finished installing the updates, you can set the language back to Brazilian Portuguese, or Danish following the same steps.

iPod 2.0: Certain Asian Characters Are Not Displayed

iPod Software 2.0 does not display certain characters.
This article has been archived and is no longer updated by Apple.

Symptom

iPod does not display certain Asian language characters. This includes some Japanese shift JIS characters, characters in the ATOK15 input palette, and some Korean characters. For example, a Japanese song called "GO(star)FIGHT(star)WIN" appears correctly in iTunes, but appears as GOFIGHTWIN on iPod.

Solution

This document will be updated when more information is available.

iPhoto: 40-Character Limit on Photo Captions When Creating a HomePage

When using iPhoto's HomePage feature to create a Web page, you are limited to 40 characters for the caption on each photo, as opposed to the 80-character limit when using Apple's HomePage feature through .Mac.
This article has been archived and is no longer updated by Apple.

Symptom

When writing captions for photos using iPhoto's HomePage feature, you cannot create photo captions longer than 40 characters.

Solution

Use iPhoto to create a "photo album" homepage with captions of 40 characters or less. If you need to create a photo caption that is greater than 40 characters, log on to the .Mac Web site (http://www.mac.com/) after creating the page in iPhoto, select the page you just created and click Edit. You will then be able to modify the photo captions, up to 80 characters each.

Final Cut Pro: How to Export Chapter Markers to DVD Studio Pro 1.5

DVD Studio Pro 1.5 translates markers placed in Final Cut Pro 3.0.2 and later as DVD chapter markers. The "What is new in DVD Studio Pro.pdf" file, included with DVD Studio Pro 1.5, incorrectly describes the steps for exporting media containing chapter and compression markers from Final Cut Pro.

This article has been archived and is no longer updated by Apple.

Enhanced Chapter Marker Feature

In addition to letting users set and move chapter markers in DVD Studio Pro, DVD Studio Pro 1.5 translates markers placed in Final Cut Pro 3.0.2 and later as DVD chapter markers. This simplifies the process of creating DVD chapter markers and ensures frame-accurate placement. There must be at least one second between chapter and compression markers or they will be ignored. When creating multi-angle material, you must place chapter and compression markers in exactly the same locations for all of the streams to be compatible. Chapter and compression markers only work with non-drop frame (NDF) timecode.

Figure 1 Edit Marker window

To insert chapter and compression markers in Final Cut Pro 3.0.2 and later projects:

1. In the Timeline, place the playhead exactly where you want to place the marker.
2. Press the M key twice to open the Edit Marker dialog.
3. Type a name for your marker. This name will be preserved when you bring the resulting MPEG-2 stream into DVD Studio Pro 1.5.
4. Click either Add Chapter Marker or Add Compression Marker. If you add a chapter marker, DVD Studio Pro 1.5 adds a chapter marker to the resulting MPEG-2 stream. If you add a compression marker, DVD Studio Pro 1.5 forces an I-frame (a video frame with no temporal compression) at the marker point, but does not add a chapter marker.
5. Click OK.
6. Repeat as needed. You can add as many as 99 chapter markers to each video stream.
7. When you have finished adding markers and are ready to export your finished project to the MPEG-2 format, choose Export from the File menu, then choose QuickTime Movie from the submenu.
8. Select MPEG-2 as the file type in the Export dialog. You can adjust the bit rate and other settings of the video by clicking Options. When you import the resulting MPEG-2 stream into DVD Studio Pro 1.5, it will have the chapter markers embedded within it.

Boris Calligraphy 1.1 and Final Cut Pro 3: Canceling Out of Title3D or Title Crawl Requires Clip Be Re-Rendered

When using the Title3D or Title Crawl features of Boris Calligraphy 1.1 with Final Cut Pro, canceling out of the Boris dialog when modifying an existing, pre-rendered clip may cause the render cache for that title to be reset, even if no changes were made.
This article has been archived and is no longer updated by Apple.

Symptom

When using the Title3D or Title Crawl features of Boris Calligraphy 1.1 with Final Cut Pro, canceling out of the Boris dialog when modifying an existing, pre-rendered clip may cause the render cache for that title to be reset, even if no changes were made.

Solution

If you encounter this situation, you must to re-render that particular title within your sequence.

This does not affect Calligraphy 1.0, where canceling an operation in the Boris dialog does not invalidate your render cache.

Note: This document contains information about third-party products. QuickTime 6: How to revert to QuickTime 5

If you have installed QuickTime 6 and wish to revert to an earlier version of QuickTime, follow the appropriate directions in this document. This article has been archived and is no longer updated by Apple.

Mac OS 8.6 through Mac OS 9

If you are using a Macintosh computer with Mac OS 8.6 through Mac OS 9 , follow the steps in "QuickTime: How to Uninstall QuickTime on a Macintosh" to remove QuickTime 6.

Once you have successfully uninstalled QuickTime 6 you should reinstall QuickTime 5, which is available from the Apple Software Downloads.

Mac OS X 10.1 through 10.1.5

If you are using a Macintosh computer with Mac OS X 10.1 through 10.1.5, follow the steps in "QuickTime 5 Reinstaller for Mac OS X: Information and Download" to remove QuickTime 6 and reinstall QuickTime 5.

Windows

If you are using a Windows-compatible computer follow the steps in "QuickTime: How to Uninstall QuickTime on a Windows-Compatible Computer" to remove QuickTime 6. When ready to install, see "QuickTime: How to Install on Windows"

Once you have successfully uninstalled QuickTime 6 you should reinstall QuickTime 5, which is available from the Apple Software Downloads.

iPhoto: Rotated Photos May Not Appear Rotated in Other Applications

Photos rotated in iPhoto may not appear rotated in other applications.
This article has been archived and is no longer updated by Apple.

Symptom

If you drag a photo rotated in iPhoto to another application, such as Mail, or to other document window, the photo is not rotated in the other application window or document.

Solution

Export the rotated photo first before using it in another application.

1. Select the photo in the iPhoto Organize or Edit window.
2. Choose Export from the File menu.
3. Click the File Export tab.
4. Change export options if desired.
5. Click Export.
6. Name and save the photo.
7. Import the saved photo into the other application or document.

Final Cut Pro 3: Imported EDLs May Need .edl Filename Extension Added

Cinema Tools exports EDL files without a ".edl" filename extension. However, Final Cut Pro only recognizes EDLs with a ".edl" filename extension. You may need to manually add it.

This article has been archived and is no longer updated by Apple.

Symptom

The EDL you are trying to import in Final Cut Pro appears dimmed in the navigation dialog and cannot be imported.

Solution

Add the ".edl" filename extension to the file before importing it into Final Cut Pro.

Published Date: Feb 18, 2012

Final Cut Pro: EDL Issue With Overlapping Transitions

This document describes an issue that can occur when importing an EDL into Final Cut Pro that references video tracks and transitions in a certain configuration.
This article has been archived and is no longer updated by Apple.

Symptom

After exporting and importing an EDL an effect may disappear when a superimposed video track has a transition that begins before the underlying track, which also has a transition that extends beyond the superimposed track. This is best understood with screenshots.

If the original timeline looks like this:

Figure 1 Original timeline

Then after exporting an EDL and importing, it will look like this:

Figure 2 Modified timeline

Solution

Add the missing effect after reconnecting the video.
Published Date: Feb 18, 2012

Final Cut Pro 3: ShuttlePRO Plug-In Not Needed

The plug-in for the Contour Design ShuttlePRO multimedia controller is no longer needed with Final Cut Pro 3. Leaving it installed can cause Final Cut Pro 3 to erroneously report that an unsupported enabler file is installed.
This article has been archived and is no longer updated by Apple.

Symptom

When opening Final Cut Pro 3 an alert box with this message appears:

> "One or more unsupported enabler files are installed. Blue render bars will appear in the Timeline to indicate areas of real-time playback that may drop frames as a result of this non-standard configuration."

Solution

Delete the Jog Enhance plug-in file which is located in the following location-

Final Cut Pro 3.0 : Plugins : Jog Enhance

The feature performed by this plug-in is part of Final Cut Pro 3.0 and later.
Published Date: Feb 18, 2012

Cinema Tools 1.0: Nested Sequences May Result In Inaccurate Cut Lists

Nested sequences in Final Cut Pro can result in inaccurate cut lists produced by Cinema Tools. Nested sequences do not maintain their relationship to the Cinema Tools database.

This article has been archived and is no longer updated by Apple.

Symptom

Cut lists created from Cinema Tools contains erroneous information such as duplicate clips.

Solution

Avoid using nested sequences when producing cut lists from Cinema Tools.

iTunes: FireWire and USB CD-R Compatibility With Mac OS 9

This document outlines which FireWire and USB CD-R drives are compatible with iTunes when used with Mac OS 9.
This article has been archived and is no longer updated by Apple.

FireWire and USB CD-R Compatibility

Making Custom CDs
Using Mac OS 9.1 or later you can create custom audio CDs that you can play in your car, portable CD player and home stereo system using iTunes. You can also make custom MP3 CDs, standard audio CDs and data CDs directly from the Finder using Disc Burner.
Â
Using FireWire and USB CD-R external drives
With Mac OS 9.1 or later you can create CDs using many FireWire and USB CD-R external drives. For better performance and reliability, use FireWire CD-R drives.

To see if your CD-R drive is supported, open iTunes then choose Preferences from the Edit menu. Click the Advanced tab. In the CD Burning section of the Preferences window, check to see if your drive is listed. If it is listed then your Macintosh recognizes and works with your CD-R drive and you can use it to burn CDs. For more information about identifying the firmware and mechanisms of your CD-R drive, see technical document 60849:"Mac OS: How to Determine a CD or DVD Drive's Mechanism and Firmware Version".
Â
FireWire and USB CD-R drives tested with iTunes
Below is a list of drives and their corresponding mechanisms and firmware that support CD burning on Macintosh computers running Mac OS 9. Some CD-R drives do not reliably play music or import songs into MP3 format. You may find that using the built-in CD/DVD drive works better for these tasks. To see a list of drives that are compatible with Mac OS X 10.2, see the storage compatiblity Web site (http://www.apple.com/macosx/upgrade/storage.html).
Â
Drive compatibility may vary due to manufacturers' use of multiple mechanisms or firmware versions in the same CD-R product. This compatibility list includes only those combinations tested by Apple.

This list assumes that you have the latest Apple CD-R burning software installed. Make sure you have installed Authoring Support Update 1.1.5, or later. It is available from Apple Software Downloads (http://www.apple.com/swupdates/).

FireWire CD-R Drives	Mechanism	Firmware
Buffalo CD-RW L8432 8x 4x 32x	Plextor PX-W8432Ti	1.08

Playing Music and Importing Songs

Some CD-R drives do not reliably play music or import songs into MP3 format. You may find that using the built-in CD/DVD drive works better for these tasks.

Â

CD Burning Tips

If you have issues burning CDs, you should use the CD-R and CD-RW media that is available from the Apple Store (http://www.apple.com/store/).

Â

Note: If you plan on using other CD burning software along with iTunes or for additional help, see the iTunes Support page (http://www.info.apple.com/usen/itunes/) or contact your drive vendor.

Disc Recording Update 1.3.4: Compatible FireWire CD-R drives

This document lists additional FireWire CD-R drives that are compatible with Disc Recording Update 1.3.4.
This article has been archived and is no longer updated by Apple.
Disc Recording Update 1.3.4 allows iTunes and the Finder to burn CD-R disc using the FireWire CD-R drives listed in the table below.

FireWire CD-R drives	Drive mechanism	Firmware version
LaCie CDRW 16x10x40 U&I	Philips CDD4911/33	B1.5
LaCie 40x12x48 U&I	CDBP-401248A	1.0
EZQuest Boa FireWire 40x12x48	Teac CD-W540E	1.0b
LaCie 40x12x48 U&I	TEAC CD-W540E	1.0B
LaCie U&I CD-RW 48x12x48	LITE-ON LTR-48125W	VS01
LaCie U&I CD-RW 40x12x48	LITE-ON LTR-40125S	ZS08
Iomega CD-RW 40x12x48	IOMEGA CDRW2304FEXT-B	ZOX2

This update requires Mac OS X 10.1.5 or later. To update to the latest version of Mac OS X, open System Preferences, choose Software Update from the View menu, then click Update Now. In the Software Update window, click the checkbox to select the items you want to install, then click Install. Type an administrator name and password. This update works with all computers that have built-in USB or built-in FireWire. ports.

CD-R drive manufacturers often use different drive mechanisms in the same CD-R drive. The drive models and mechanisms listed above are the only combinations tested and approved by Apple.

For the latest information and answers to technical support questions, see the Apple Support Web site (http://www.apple.com/support/).

QuickTime 6: About QuickTime Pro Keys

This document discusses QuickTime 6 Pro keys.
This article has been archived and is no longer updated by Apple.

What is QuickTime Pro?
QuickTime Pro is an upgrade to QuickTime that unlocks editing and creation features that enable you to:

- Create slide shows with images from a digital camera
- Build Media Skins to display your media files in a custom environment
- Encode and transcode media in dozens of formats, including MPEG-4
- Edit using simple cut, copy, and paste functions
- And much more

To get the most out of QuickTime Pro, take a look at the helpful books and CD-ROMs about QuickTime on the QuickTime Tools & Tips page.

Can I automate workflows?
On a Macintosh, you can use AppleScript and QuickTime Pro to automate most any workflow, from the simple to the complex. Visit the Apple Script website for hundreds of QuickTime-compatible scripts.

Will my QuickTime 4 or 5 Pro key work with QuickTime 6?
Because QuickTime 6 includes royalty-bearing technologies, a new QuickTime Pro key is required to unlock Pro functionality in QuickTime 6. If your key no longer works, visit the Apple Store to purchase a new one.

I want to use my QuickTime 4 or 5 Pro key, but I've installed QuickTime 6. What do I do?
You'll need to run an earlier version of QuickTime, which are available from the Apple Support website.

Will a QuickTime Pro key for Windows work on a Mac, and vice versa?
No. QuickTime Pro keys are platform-specific. Windows keys will work on all supported Windows platforms. Macintosh keys will work on all supported Mac operating systems, including Mac OS X.

How do I enter my registration key?
Keys are entered in the QuickTime Registration panel, either in the QuickTime control panel (Mac OS 8.6, 9, and Windows) or QuickTime Preferences (Mac OS X). For detailed instructions, visit the QuickTime key install help site.

I've lost my QuickTime Pro key. What should I do?
If you bought your QuickTime Pro key in the Apple Store, visit the Apple Store again and log in using your account. Visit the Software Purchases area to retrieve your key. If you did not buy it in the Apple Store or you don't see your key when you log in to the Apple Store, call your local store's telephone number.

I have my key but have lost the program. How can I get it again?
Simply download QuickTime for free from the QuickTime Download page. During the installation process you will be prompted to enter your username and key, which will unlock QuickTime Pro.

iTunes: About Using Audible Spoken Word Files

You can use iTunes 3 and iTunes 4 to listen to Audible spoken word files, including audio books, spoken magazines, and newspapers.
This article has been archived and is no longer updated by Apple.
iTunes 3 and iTunes 4 can play Audible spoken word files (format 2, 3, and 4 only). For more information about these files, see the Audible Web site (http://www.audible.com/).

Once you have downloaded an Audible file, you can add it to your iTunes library just like you add any other file. **Note:** iTunes does not have a feature that allows you to listen to streaming Audible files.

To make sure that iTunes is selected as the application you want to use to listen to Audible files:

1. Quit all other Internet applications
2. Open iTunes
3. Choose iTunes > Preferences
4. Click General (if necessary)
5. Click Set.
6. Click OK

If an Audible file does not open in iTunes when you double-click it, you can open the file by dragging its icon on top of iTunes' icon in the Dock.

Using Audible files with iTunes counts as an additional Audible account. If you have exceeded your account limit, contact Audible for help.

iTunes can only sync Audible files to iPod. It cannot sync them to other kinds of portable players that are compatible with iTunes.

If you connect iPod to a computer using iTunes 2, iPod won't be able to play Audible files until you connect it to a computer using iTunes 3 or later. **Important:** In order to play Audible files on iPod, you must install iPod 1.2 software or later.

iTunes 3: Before You Install

This document outlines steps you should take before installing iTunes 3.
This article has been archived and is no longer updated by Apple.
Before you install iTunes 3, you should:

- Quit iTunes 2 if it is open.
- Delete the iTunes 2 application if you dragged it outside of the Applications folder. If you do not delete it before installing, some files, including Help files, may not be updated correctly. The Read Me file for iTunes 3 states that you should delete iTunes 2 before installing iTunes 3. This is only necessary if you dragged the file outside the Applications folder.
- Consider updating your iPod to iPod Software 1.2 or later (when it becomes available) in order to take advantage of the feature of iTunes 3.
- Make sure you don't have an empty iTunes folder in the Music folder. If you have created a folder named "iTunes" in your Music folder, iTunes 3 will use that folder for your music library. If your music library is not in the ~Music/iTunes/ folder and is in the Documents folder instead, your library will appear to be empty. Quit iTunes 3, rename the folder to "iTunesOld", for example, and reopen iTunes 3.

iPod Software 1.0 with MusicMatch: How to Uninstall

This document explains how to uninstall or "remove" iPod for Windows Software 1.0.
This article has been archived and is no longer updated by Apple.
Follow these steps to uninstall iPod for Windows Software 1.0.

1. Open the Control Panel.

2. Double-click Add/Remove Programs. The Add or Remove Programs window appears. See Figure 1.

Figure 1 Add or Remove Programs window

3. Click Change or Remove Programs, if necessary.

4. Select iPod for Windows in the "Currently installed programs" list.

5. Click Change/Remove. The InstallShield Wizard opens. See Figure 2.

Figure 2 InstallShield Wizard window

6. Click Remove, then click Next.

7. Click OK to confirm that you want to uninstall the software. A Setup Status panel informs you of the progress. Once it is finished, the iPod for Windows Software is removed.

Note: You can follow these steps to uninstall the MUSICMATCH iPod Plug-in and theMUSICMATCH Jukebox software that were installed by the same installer as the iPod for Windows Software.

Published Date: Feb 18, 2012

iPod for Windows Software 1.0: How to Format iPod‘s Hard Disk

This document explains how to format iPod's hard disk so you can use it with a Windows-compatible or Macintosh computer.
This article has been archived and is no longer updated by Apple.

Formatting the disk for Windows

1. Make sure your computer meets the system requirements to use iPod for Windows Software 1.0. For more information on the system requirements, see technical document 60971, "**iPod: System Requirements**."

2. Find the iPod for Windows Software 1.0 CD-ROM disc that came with your iPod, and insert it into your computer's disc drive. **Note:** This software is not available to download from Apple's Web site.

3. Install iPod for Windows Software 1.0. For more information see technical document 61669, "**iPod for Windows Software 1.0: How to Install**".

4. Connect iPod to your computer using the FireWire cable that came with iPod. If your computer does not have a FireWire port see the Apple Store (http://www.apple.com/store/) for compatible FireWire cards you can install in your computer.

5. Open Updater and restore the software.
    1. Choose the Updater from the Start menu: Programs > iPod.
    2. Click Restore.
    3. Follow the directions on the screen.

After following these steps, iPod's hard disk has been formatted as FAT32, and will work with computers that have a compatible version of the Windows operating system.

To verify that iPod has been formatted for Windows, see technical document 61672, "**iPod 1.2: How to Determine iPod's Hard Disk Format**".

Formatting the disk for Macintosh

If you have installed iPod for Windows Software on iPod, and want to change it so that it only works with a Macintosh, you will need to restore iPod using the Macintosh version of the iPod Software Updater.

For more information on the how to restore iPod with the Macintosh version of iPod Software Updater see technical document 60983: "**iPod: How to Restore**."

Published Date: Feb 18, 2012

iPod Software 1.2: Differences Between Mac and Windows Versions

This document outlines the differences between iPod 1.2 software for Macintosh and Windows.
This article has been archived and is no longer updated by Apple.
Due to differences between iTunes 3 and MusicMatch software, the following iPod 1.2 features are not available when iPod for Windows Software 1.0 is installed:

- Audible.com spoken word file playback
- Sound Check
- browse by composer
- play counts
- play dates
- my rating
- per-song EQ settings (general EQ settings work as expected.)
- Smart Playlists

Note: MusicMatch Jukebox, included with iPod for Windows, has an feature called Volume Leveling that is similar to Sound Check. However, the Volume Leveling feature is not part of iPod for Windows Software 1.0. Using Volume Leveling has no effect when playing songs on iPod.

iPod for Windows: If FireWire does not charge iPod

If iPod doesn't charge when you connect it to your computer, you should connect it to the Apple iPod Power Adapter instead.
This article has been archived and is no longer updated by Apple.

Symptom

- iPod doesn't charge when you connect it to your computer.
- The clock frequently needs to be reset.
- iPod doesn't shut off while connected to a Windows-compatible computer that goes to sleep.
- iPod doesn't go into Disk Mode while connected to a Windows-compatible computer that went to sleep and then awoke.

Products affected

- iPod for Windows

Solution

The FireWire (IEEE 1394) ports on some Windows-compatible computers may not be powered, and may not charge iPod when you plug it in. A port that only accepts a 4-pin cable is not powered.
6-pin FireWire port and icon

4-pin FireWire port and icon (requires separate adapter and does not charge iPod)

To determine you can charge iPod with your computer's FireWire port:

1. Connect iPod to your computer using the iPod FireWire cable. You may need to use a 4-pin to 6-pin FireWire adapter.
2. Check to see if iPod's battery charge indicator in the top right corner is animating. If so, iPod is charging. If not, it is not charging. You should connect iPod to the Apple iPod Power Adapter instead, especially before using it with your computer.

To charge iPod using the Apple iPod Power Adapter:

1. Disconnect iPod from your computer.
2. Connect iPod to the power adapter using the FireWire cable that came with iPod.
3. Plug in the power adapter to a working electrical outlet.

iPod will indicate when the battery is fully charged.

Tip: iPod mini and iPod (Click Wheel) can also charge while connected via a high-powered USB 2.0 port.

QuickTime 5 for Windows: QuickTime Player Unexpectedly Quits

QuickTime Player may unexpectedly quit if you have installed and uninstalled a series of different versions of QuickTime 6 and QuickTime 5.
This article has been archived and is no longer updated by Apple.

Symptom

QuickTime Player 5 may unexpectedly quit if you have done the following:

1. installed QuickTime 6 Public Preview
2. added a favorite .mp4 movie
3. upgraded to the final version of QuickTime 6.0
4. uninstalled QuickTime 6
5. installed QuickTime 5

Solution

Delete the QuickTimeFavorites.qtr file. It is located in these locations:

Windows NT: C:\\WINNT\\profiles\\All Users\\Application Data\\QuickTime
Windows 98 and Me: C:\\Windows\\All Users\\Application Data\\QuickTime
Windows 2000 and XP: C:\\Documents and Settings\\All Users\\Application Data\\QuickTime

WebObjects 5.1: How to Find the Version of WebObjects and Other Software Installed in Mac OS X

This document provides sample Java code to extract the version of each software package installed on the Mac OS X computer without having to look for the version number of each package in the directory `/Library/Receipts`.
This article has been archived and is no longer updated by Apple.
The sample function can be defined in any class suitable to your program.

The use of this software is subject to the conditions set out in the license.txt file:

THE SOFTWARE PATCH PROVIDED FROM APPLE IS PROVIDED "AS IS" AND WITHOUT WARRANTY, EXPRESS OR IMPLIED. APPLE SPECIFICALLY DISCLAIMS ANY IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT WILL APPLE BE LIABLE FOR ANY DAMAGES, INCLUDING BUT NOT LIMITED TO ANY LOST PROFITS, LOST SAVINGS OR ANY INCIDENTAL OR CONSEQUENTIAL DAMAGES, WHETHER RESULTING FROM IMPAIRED OR LOST DATA, SOFTWARE OR COMPUTER FAILURE OR ANY OTHER CAUSE, EVEN IF APPLE IS ADVISED OF THE POSSIBILITY OF SUCH DAMAGES, OR FOR ANY OTHER CLAIM BY CUSTOMER OR FOR ANY THIRD-PARTY CLAIM.

Sample Code

In this example, the method

```
public static NSDictionary productVersions()
```

is defined in the file Application.java in a WebObjects application project.

```
import java.io.*;
import com.webobjects.foundation.*;
import com.webobjects.appserver.*;
import com.webobjects.eocontrol.*;

public class Application extends WOApplication {

      private static NSDictionary _productVersions = null;

    public static void main(String argv[]) {
        WOApplication.main(argv, Application.class);
    }

    public Application() {
        super();
        System.out.println("Welcome to " + this.name() + "!");

        /* ** Put your application initialization code here ** */

         System.out.println("Version information:\\n" +
            formattedDictionary(productVersions()));
    }

    public static NSDictionary productVersions() {
        if ( _productVersions != null) return _productVersions;

        // Go to the /Library/Receipts directory to get the software version
        String receiptsDirString = "/Library/Receipts";
        File receiptsDir = new java.io.File(receiptsDirString);

        if (!receiptsDir.exists() || !receiptsDir.canRead())
            return NSDictionary.EmptyDictionary;

        // Extract the version information from each package Contents,
        // Resources folders and software_version file
        try {
            String packageFiles[] = receiptsDir.list();
            int length = packageFiles.length;
            NSMutableDictionary packages = new NSMutableDictionary(length);

            for (int i = 0; i < length; i++) {
                String packageName = packageFiles[i];
                String packagePath = receiptsDirString + "/" + packageName +
                    "/Contents/Resources/software_version";
                File versionFile = new File(packagePath);

                if (versionFile.exists()) {
```

```
                    StringBuffer versionString = new StringBuffer();
                    try {
                        LineNumberReader reader = new LineNumberReader(
                            new InputStreamReader(
                            new FileInputStream(versionFile)));
                        String line = reader.readLine();

                        while (line != null) {
                            versionString.append(" " + line);
                            line = reader.readLine();
                        }
                    }
                    catch (IOException e) {
                        // Flag the exception and return an empty string
                        System.out.println("Raised IOException");
                        return NSDictionary.EmptyDictionary;
                    }
                    if (versionString.length() > 1) {
                        String packageVersion = versionString.substring(1);
                        NSArray packagesForVersion =
                            (NSArray)packages.objectForKey(packageVersion);

                        if (packagesForVersion == null) {
                            packages.setObjectForKey(new NSArray(packageName),
                                packageVersion);
                        }
                        else {
                            NSMutableArray packageVersHolder =
                                new NSMutableArray(packagesForVersion);
                            packageVersHolder.addObject(packageName);
                            packages.setObjectForKey(packageVersHolder,
                                packageVersion);
                        }
                    }
                }
            }
            _productVersions = packages;
            return _productVersions;
        } catch (SecurityException e) {
            return NSDictionary.EmptyDictionary;
        }
    }

    // Make product versions dictionary more readable by alphabetizing by
    // package name and writing each package on its own line.
    public static String formattedDictionary(NSDictionary aDict) {
        String packageVersionString = aDict.toString();
        packageVersionString = packageVersionString.substring(1,
            packageVersionString.length() - 2);
        NSArray packageStrings =
            NSArray.componentsSeparatedByString(packageVersionString, "; ");
        try {
            packageStrings = packageStrings.sortedArrayUsingComparator(
                NSComparator.AscendingStringComparator);
        } catch (NSComparator.ComparisonException e) {
        }
        return packageStrings.componentsJoinedByString(";\\n");
    }
}
```

Usage

The _productVersions NSDictionary contains the following:

- The keys are the version strings for the different packages.
- The values are the packages for that version string.

Using the above code will generate the following output:

```
Version information:
{
    "DVDPlayerUpdate 3.1.1 (build 1B203)" = (DVDPlayerUpdate.pkg);
    "Epson Print Drivers 1.1 1.1 (build 4L13)" = (EpsonPrintDrivers.pkg);
    "Mac OS X 1.0 (build 5S66)" = (NetworkingUpdate.pkg);
    "Mac OS X 1.0 (build 5U6)" = (SecurityUpdateJuly2002.pkg);
...
```

Final Cut Pro 3: Cursor Artifacts With Mac OS X 10.2

When using Final Cut Pro 3 with Mac OS X 10.2, you may notice some artifacts near the cursor when playing material in the Viewer. This only occurs with NVIDIA video cards.

This article has been archived and is no longer updated by Apple.

Symptom

You see slight distortion near the cursor when playing material in the Viewer.

Solution

The artifacts are purely cosmetic and can be ignored.

Published Date: Feb 18, 2012

iPod 1.2: Backlight Briefly Turns on at Midnight

iPod's backlight may briefly turn on at midnight.
This article has been archived and is no longer updated by Apple.

Symptom

The backlight turns on for about a second at midnight (00:00).

Solution

The iPod's internal clock is adjusted at midnight. During the adjustment, the backlight may briefly turn on for a second. You can prevent this by turning off the backlight feature. Choose Settings > Backlight timer > Off. The brief amount of time the backlight turns on does not affect overall battery performance.

iPod 1.2: iPod Scripts for Mac OS X 10.1 Do Not Import Contacts

This article has been archived and is no longer updated by Apple.

The iPod Scripts for Mac OS X 10.1 that were posted on the AppleScript Web site do not work with iPod 1.2 software, or with Mac OS X 10.2.

Symptom

- With Mac OS X 10.2, the iPod scripts do not open.
- With Mac OS X 10.1 through 10.1.5 the iPod scripts seem to work, but only the first contact appears on iPod. The other contacts that were imported using these scripts do not appear.

Products affected

- iPod software 1.2
- Mac OS X 10.2
- Mac OS X 10.1 through 10.1.5

Solution

Do not use these scripts to import contacts if you are using Mac OS X 10.2 (or later) or iPod Software 1.2 (or later).

If you have used these scripts with iPod Software 1.1 and then upgraded to iPod Software 1.2, follow the instructions in these technical documents to remove the current contacts file and reload contacts:

About the Do not disconnect and OK to disconnect screens for iPod

This article has been archived and is no longer updated by Apple.

Learn about the disconnect screens that are part of iPod software.

iPod has two disconnect screens. They let you know when it is safe to unplug iPod from your computer's USB or FireWire port. Incorrectly disconnecting iPod while it is in use can damage data on iPod, or the computer's hard disk.

The first screen appears when you connect iPod to the computer.

"Do not disconnect" screen.

As long as iPod is connected to the computer, and you have not ejected it from the Finder or iTunes, the "Do not disconnect" screen appears.

To disconnect iPod from your computer, you must first eject it. Follow the instructions in "**Disconnecting iPod from your computer**". Once you have ejected iPod, the second disconnect screen appears.

"OK to disconnect" screen

You may now safely unplug the FireWire or USB cable from iPod.

1. When you first connect iPod to your computer, the "OK to disconnect" screen may briefly appear until the computer recognizes iPod is connected. This is normal.
2. These screens do not appear if your computer is in sleep mode. Wake your computer before disconnecting iPod.
3. These screens do not appear if iPod is connected to the Apple iPod Power Adapter. You may disconnect iPod from the Apple iPod Power Adapter at any time.

If your iPod displays this message but is not connected to a computer, or another device such as iPod Camera Connector, reset it to remove it from disk mode.

To avoid this behavior in the future, make sure that you safely disconnect your iPod prior to disconnecting it from your computer.

iPod (touch wheel): Jumpy or erratic touch wheel operation

This document explains how to get the best performance from iPod's touch wheel
This article has been archived and is no longer updated by Apple.

Symptom

iPod's touch wheel seems to behave erratically jumping from one menu to another.

Solution

The iPod touch wheel models do not have a scroll wheel. They have a touch wheel. See Figure 1.

Figure 1 iPod touch wheel

With no moving parts, the touch wheel is more durable than the scroll wheel, and less vulnerable to dust, dirt, or sand.

The touch wheel, like the trackpad on an iBook or PowerBook, works on the principle of coupling capacitance. It relies on the electrical charge in your finger to measure movement. As your finger moves over the surface, the touch wheel evaluates the change in capacitance between two layers of measurement electrodes built into the surface of the touch wheel, and translates that to menu movement.

To assist with touch wheel issues:

- Make sure that only one part of your finger touches the touch wheel. You cannot use a pen or other object--the touch wheel is designed to work only with a finger. Also make sure that you are not resting another finger on or very close to the touch wheel. The touch wheel may interpret this as the other finger touching it, and make the wheel react as if moved in that direction. If you suspect either of these is causing the your issue, set the iPod on a table or flat surface, and then raise your wrist in the air and touch the touch wheel with only the tip of a finger. If the symptom goes away, you know that one of the above is the cause: you need to adjust the position of your finger or manner of handling.
- If you are in a very humid environment that causes moisture to collect on the touch wheel, or your hands are damp from being washed or exercise, the touch wheel may act erratically. Using a soft dry cloth or tissue (without lotion) dry off the touch wheel. In some very humid environments, you may need to use, as a temporary measure, a dry tissue (without lotion) or thin piece of paper over the touch wheel. As with all Apple products, iPod was only designed to function properly in certain operating and storage environments. These specifications are listed in iPod's User Manual.
- Oil or lotion can cause the same issue as moisture. Remember, some tissues have lotion, and some cleaning-cloth materials may leave a residue, causing the touch wheel to work poorly.
- Jewelry may also cause interference. Try removing rings or bracelets to see whether the jumpy or erratic behavior disappears.
- For best control, you should move your finger all the way around the touch wheel, instead of making small movements in the same spot.

Note: With the scroll wheel, some users used the Select button to turn the wheel. This does not work with the touch wheel.

iPod 1.2: About the Browse Menu

This document describes the Browse menu in iPod Software 1.2.
This article has been archived and is no longer updated by Apple.
iPod Software 1.2 introduces the Browse menu. It is available from the main menu. See Figure 1.

Figure 1 iPod 1.2 Browse menu

In the Browse menu you choose to view songs by Artists, Albums, Songs, Genres, or Composers.

Artists

This menu choice displays a list of all the different artists in iPod's music library. It works the same as in iPod Software 1.1, but is now located in the Browse menu.

Albums

This menu choice is new to iPod Software 1.2. It is a quick way to see a list of all the albums stored on iPod. As with iPod Software 1.1, you can see this same album list by selecting Artists, then All.

Songs

This menu choice displays a list of all the song titles in the iPod's music library. It works the same as in iPod Software 1.1, but is now located in the Browse menu.

Genres

This is new to iPod Software 1.2. When selected, it lists all the different genres that are stored in iPod. Genre is an ID3 tag that you can set in iTunes.

Composers

This option is new to iPod Software 1.2 and iTunes 3. The composer tag can be used to distinguish several versions of the same song written by the same composer, but performed by different artists.

Examples

1. Two versions of Prokofiev's Piano Concerto no. 3 are stored on iPod. One is performed by Martha Argerich, and the other by Yefim Bronfman. The Composer tag for each song is filled in with Sergei Prokofiev. The Artist tag is filled in by the unique artist playing Piano Concerto no. 3.

2. Another use of the composer tag is to identify the DJ of a DJ-mixed album. These albums consist of songs performed by different artists that are mixed together (compiled) by a DJ. By entering the DJ's name as the composer, the song's artist can be populated in the Artist tag.

iPod 1.2: About the Clock

This document describes the Clock feature in iPod Software 1.2, and explains how to set the clock and make other settings.
This article has been archived and is no longer updated by Apple.
iPod Software 1.2 introduces a Clock feature. It displays the time and date.

Follow these steps to view the clock:

1. Select Extras from the main menu.
2. Select Clock from the Extras menu.

Important: iPod does not have a backup battery to preserve the date and time if the battery fully discharges. If that happens, you should charge the battery, then reset the time and date.

Clock Synchronization with Mac OS X

If you connect iPod to a computer that has Mac OS X 10.2 (or later) installed, iPod's clock is synchronized to the date and time of the computer. This does not require that you open iTunes. **Note:** If the computer's date and time are incorrect, iPod's clock will also be incorrect.

Clock Settings

There are two settings that are associated with the clock that can be changed in the Date & Time settings:

- Set Time Zone
- Set Date & Time

Set Time Zone

Follow these steps to set the time zone:

1. Select Settings from the main menu.
2. Select Date & Time from the Settings menu.
3. Select Set Time Zone from the Date & Time menu.
4. Select your time zone from the list.

Important: The "time zones" that iPod uses are not really time zones. They are Universal Coordinated Time (UTC) offsets. For this reason, several actual time zones are "missing" (such as the three Australian and New Zealand time zones). If your time zone is not listed, you should choose the city/zone/place that represents the UTC offset for your time zone.

Time Zones for regions are not in alphabetical order. They are in "world order," starting at the international date line and moving eastward.

When using iPod's Calendar, it is important that the time zone be set correctly for the calendar alarms to work.

Set Date and Time

Follow these steps to set the date and time:

1. Select Settings from the main menu.
2. Select Date & Time from the Settings menu.
3. Select Set Date & Time from the Date & Time menu. The hour will highlight, displaying up and down arrows.
4. Scroll to change the hour, then press Select. Each setting will highlight in turn, and you set it in the same fashion.
5. After setting the year, press the Select button to return to the Date & Time menu.

There are no settings to change the way either the date or time is displayed. You cannot choose to display a 24-hour clock, and if you choose English as your default language, the date will be displayed as DD Month YYYY.

Depending on the language iPod is set to use, the date and time format will change accordingly.

Mac OS X 10.2: iTunes 3 May Not See iPod if Its Name Is Changed

On a computer with Mac OS X 10.2 installed, your iPod will not appear in the iTunes 3 Source list if you renamed it since iTunes 3 was last opened.
This article has been archived and is no longer updated by Apple.

Symptom

iPod does not appear in the Source list.

Solution

This issue is addressed in Mac OS X 10.2.1. For more information on installing the latest updates for your computer, see technical document 106704, "**Mac OS X: How to Update Your Software**".

Macintosh LC and Macintosh IIsi: Sound Input

Article Change History

06/21/93 - REVIEWED
* To confirm specifications of Sony and Radio Shack cables.

This article is about the sound input circuitry for the Macintosh LC and Macintosh IIsi.

This article has been archived and is no longer updated by Apple.
The Macintosh LC and Macintosh IIsi computers have built-in mono 8-bit sound input circuitry. This hardware is supported by the System 7.0 Sound Manager, which is included in System 6.0.7.

An electret microphone and a plastic holder to attach the microphone to the front of a monitor are included with the system. The microphone has a male miniature stereo phone connector. Customers can use any commercially available microphone that does not require an external power source.

An attenuated RCA adapter cable, with a male miniature phone connector on one end and two female RCA connectors on the other steps down the voltage level of the incoming signal. Devices such as CD players or tape players provide line out signals at a higher level than the 20 millivolt - 600-ohm impedance expected by the sound input circuitry. If you use a non-attenuated RCA adaptor cable in the audio-in jack, you will not hurt the system and it will still digitize the signal, but it may be very distorted.

If you use an attenuated RCA adapter cable as an audio-out cable, it may or may not work, depending on what you're connecting to. A standard RCA adapter cable is recommended for audio out. If the microphone is plugged into the audio-out jack, no sound will come out of the jack or the internal speaker.

Both Sony and Radio Shack sell attenuated RCA cables. The Sony part number is RK-G128 and the Radio Shack part number is 42-2461-A.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Final Cut Pro 3: Get IHA Utility Doesn‘t Recognize Double-Byte Computer Names

The Academic Lab version of Final Cut Pro 3 comes with a utility called Get IHA Carbon, which assists in the creation of the list of authorized computers. When using this utility in Mac OS X, computers with names that contain double-byte characters (such as any Japanese character) do not appear in the list of authorized computers.
This article has been archived and is no longer updated by Apple.

Symptom

The computer name does not appear in the Lab Machine List after using the Get IHA Carbon utility.

Solution

- Remove double-byte characters from the Computer Name in the Sharing preference pane.

OR

- Start the computer from Mac OS 9 and use the Get IHA PPC utility instead.

iPod for Windows Software 1.0: Read Me

This document contains the Read Me file for iPod for Windows Software 1.0.
This article has been archived and is no longer updated by Apple.

About iPod for WindowsÂ®

iPod for Windows includes MUSICMATCH Jukebox Plus software equipped with plug-in software for Apple's iPod. Use MUSICMATCH Jukebox Plus and the iPod plug-in software to organize music from your CD collection, then transfer songs to iPod for listening on the go. For more information go to http://www.apple.com/ipod/ .

Requirements

To use iPod for Windows, you must have a PC with the following:

- A 300 MHz Pentium (or better) microprocessor
- MicrosoftÂ® Windows MEÂ®, Windows 2000Â®, or Windows XPÂ®
- Built-in or Windows-certified FireWire card (IEEE 1394)
- At least 96 MB RAM (at least 128 MB for Windows XP)

How to install

Insert the iPod for Windows CD. The installer should run automatically. If it does not, open the CD-ROM icon in My Computer and double click the Setup icon. Click the "Install" button in the installer window and follow the on screen instructions to complete the registration and installation of the iPod for Windows software.

Don't forget to use the MUSICMATCH Jukebox Plus registration number included on the CD packaging to register your copy of MUSICMATCH Jukebox. The registration will allow you to make use of all of the features of MUSICMATCH Jukebox Plus for free, a 19.99 USD value!

For more information

MUSICMATCH Jukebox includes extensive built-in help about using the application and about using iPod. To access iPod Help, open MUSICMATCH Jukebox and choose MUSICMATCH Jukebox Help from the Help menu. Then click Apple iPod Help. For MUSICMATCH support online, go to http://www.musicmatch.com/ .

In addition, the Apple Support web site is available to help you 24 hours a day, 7 days a week. You'll find comprehensive product information as well as technical assistance and software updates. Apple's Knowledge Base contains current and recent product technical information, troubleshooting tips, and how-to articles. Apple Discussions offers a variety of forums for product-specific information and feedback. For more information, go to http://www.apple.com/support/ipod/ .

We value your input. To submit feedback on iPod for Windows software, go to **http://www.apple.com/feedback/ipod.html** . (**Note:** The URL in the Read Me file included with iPod was incorrect.)

iPod for Windows with MusicMatch: iPod synchronizes, but there are no songs or playlists

You use MUSICMATCH Jukebox to synchronize iPod in Windows, but there are no songs or playlists on iPod when the update is complete.
This article has been archived and is no longer updated by Apple.
This can happen if you have enabled the "Selected playlists synchronization," option, but did not select a playlist(s).

Select one or more playlists that contain songs, then perform the synchronization.

iPod with MusicMatch: Installation Troubleshooting Steps

This document lists steps that may help you resolve issues installing iPod for Windows software.
This article has been archived and is no longer updated by Apple.
Follow these steps to troubleshoot the installation of iPod for Windows software:

1. System Requirements
Make sure your computer meets the system requirements to use iPod for Windows. See technical document 60971, "**iPod: System Requirements**".

2. Make sure you are logged in as a Windows Administrator user if you're using Windows 2000 or Windows XP.

3. Make sure the iPod for Windows CD is not dirty or scratched.

4. Quit out of all other application programs before installing.

5. Quit of the Installer and try to install again.
If you accidentally started several instances of the Installer, quit out of all instances before opening the Installer again.

6. Restart your computer.

7. Earlier version of MUSICMATCH Jukebox
If you already have an earlier version of MUSICMATCH Jukebox installed, and are having issues installing the version that came with iPod for Windows, uninstall (remove) the previous version of MUSICMATCH Jukebox, and then install the iPod for Windows software. To uninstall MUSICMATCH Jukebox, click 'Start' from your Windows Taskbar, go to 'Settings/Control Panels/Add/Remove Programs' and select MUSICMATCH Jukebox from the Install/Uninstall tab.

8. Do not Change Focus
If you change focus off the installer onto another application, some of the user interface elements of the Installer may not function properly, such as pop-up menus. If this happens, try double-clicking the Back button twice, and then click Next to refresh the Installer window.

9. Must Install on C Drive
iPod for Windows software must be installed on the C drive in order to work.

iPod: Does Not Appear in MUSICMATCH Jukebox

This document lists steps you can take when your computer recognizes iPod, but MUSICMATCH Jukebox does not.
This article has been archived and is no longer updated by Apple.

Symptom

Your computer recognizes iPod when you connect it to the FireWire port, but MUSICMATCH Jukebox does not.

Solution

In MUSICMATCH Jukebox, your iPod should appear in the PortablePlus window under the Attached Portable Devices folder.

Figure 1 PortablePlus window

If the PortablePlus window is not open, you can open it by choosing "Download Files to Portable Devices" from the File menu.

If iPod does not appear in MUSICMATCH Jukebox's Attached Portable Device folder list, follow these steps in order until iPod appears. When iPod appears, you can stop.

System requirements
Make sure your computer meets the system requirements to use iPod for Windows. See technical document 60971, "**iPod: System Requirements**".

Must be iPod for Windows
iPod for Windows Software will only recognize iPod for Windows. You cannot use iPod for Macintosh with a Windows-compatible computer. To see which model of iPod you have, follow the instructions in technical document 61672, "**iPod 1.2: How to Determine iPod's Hard Disk Format**".

iPod charged or getting power
iPod must either be getting power from the FireWire bus, or have a charge for it to be recognized. For more information see technical document 61676, "**iPod for Windows: Does Not Charge When Connected to Your Computer**".

Quit and re-open MUSICMATCH Jukebox
Quit MUSICMATCH Jukebox, then re-open it.

Restart the computer
Restart your Windows computer.

Reconnect iPod
If you see the "OK to disconnect" screen on iPod:

1. Unplug iPod.
2. Wait until iPod displays the Main menu.
3. Plug iPod back in to the computer.
4. Open MUSICMATCH Jukebox if it does not open by itself.

If you see the "Do not disconnect" screen on iPod:

1. Eject or "unmount" iPod using one of the recommended ways listed in technical document 61724, "**iPod for Windows: How to Eject and Disconnect iPod From Your Computer**"
2. Unplug iPod.
3. Wait until iPod displays the Main menu.
4. Plug iPod back in to the computer.
5. Open MUSICMATCH Jukebox if it does not open by itself.

Reset iPod
Reset iPod. For more information see the technical document 61705, "**iPod: How to Reset**".

Restore iPod
Restore iPod. For more information see technical document 60983, "**iPod: How to Restore**". **Warning:** The restore process cannot be undone

and all of your data and music will be deleted. You should always keep a backup of all of your important data.

Software installed/reinstall
Make sure the iPod for Windows software is installed from the iPod for Windows CD that came with iPod. Verify that the iPod Watcher appears in the system tray. Reinstall the iPod for Windows software. For more information see technical documents 61669, "**iPod for Windows Software 1.0: How to Install**" and 61817, "**iPod for Windows 2.0: How to Install**".

Important: iPod for Windows software must be installed on the C drive.

Install/remove FireWire drivers
The FireWire card drivers included with Windows XP may work with your computer's FireWire card. In some cases, the card's manufacturer may publish later drivers with better performance than those included with Windows XP. If you have followed the other troubleshooting steps in this document, and iPod still does not appear in MUSICMATCH Jukebox, consider installing these drivers, which are generally included on a CD-ROM disc with the card, or are available from the manufacturer's website. If you have already installed them, consider removing them and using the drivers included with Windows XP instead.

iPod for Windows with MusicMatch: How to Eject and Disconnect iPod From Your Computer

This document explains how to correctly eject or "unmount" iPod from a Windows-compatible computer.
This article has been archived and is no longer updated by Apple.
When iPod is used as an external FireWire hard disk, or is set to Manually Update, you must correctly eject it before you unplug the FireWire cable to protect the data on iPod, and on your computer. You should never disconnect iPod from any computer while iPod's screen says "Do not disconnect". Disconnecting in this state could damage data.

There are several ways to properly eject iPod in the Windows operating system:

- Eject button in MUSICMATCH
- Safe Remove Hardware in the system tray
- iPod Watcher in the system tray

Eject button in MUSICMATCH

Follow these steps to eject the iPod from within the Music Match Jukebox application.

1. Select iPod in the MUSICMATCH Jukebox PortablesPlus window:

Figure 1 PortablePlus window

2. Click Eject at the lower-left of the MUSICMATCH Jukebox PortablesPlus window:

Figure 2 Eject button in PortablePlus window

3. An alert box appears. Click Yes.

4. There is about a 15 second wait before iPod is ejected . The MUSICMATCH Jukebox PortablesPlus window displays two status messages: "Ejecting iPod. Please wait..." and "It is now safe to disconnect iPod."

5. When iPod has been ejected, the screen says, "OK to disconnect."

6. Unplug iPod.

Safe Remove Hardware in the system tray

Follow these steps to eject the iPod using the Unplug or Eject Hardware Tool in the Windows System Tray.

Follow these steps to eject iPod using the Safely Remove Hardware icon in the system tray:

1. At the bottom-right of the screen, click the "Safely Remove Hardware" icon:

Figure 3 "Safely Remove Hardware" icon

2. Click the pop-up menu. In this example for Windows Me it reads, "Stop IEEE 1394 Disk-Drive[F:]"

Figure 4 Pop-up menu

3. When the Safe To Remove Hardware message appears, click OK.

4. Make sure you see the "OK to disconnect" screen on iPod, then disconnect it from the computer.

iPod Watcher in the system tray

Follow these steps to eject iPod using the iPod Watcher icon in the system tray:

1. Make sure no applications are using iPod, including MUSICMATCH Jukebox.

2. Click the iPod icon in the system tray, and choose Unmount from the pop-up menu.

Figure 5 iPod Watcher in the system tray

3. An alert box appears. Click OK.

4. Make sure you see the "OK to disconnect" screen on iPod, then disconnect it from the computer.

Do not use right button on mouse to eject iPod

Warning: You should not use the contextual menu eject option by right-clicking on the iPod hard disk icon in the My Computer window.

Figure 6 Contextual menu that appears when you right-click iPod's hard disk icon

iCal 1.0: Dragging Calendar Name to Finder Does Not Export It

iCal Help indicates that you can export a calendar by dragging its name to the Finder. This feature is not available in iCal 1.0.
This article has been archived and is no longer updated by Apple.

Symptom

When you drag a calendar's name to the desktop or a Finder window, nothing happens. The calendar is not exported even though iCal's Help document indicates that it should work.

Solution

The iCal help content is in error. This feature is not available in iCal 1.0. To export a calendar, click its name to select it, then choose Export from the File menu.

QuickTime 6 for Windows: Does Not Save Favorites and Recent Items

Some Windows-compatible computers with QuickTime 6 do not save items in the Open Recent menu and Favorites list.
This article has been archived and is no longer updated by Apple.

Symptom

The Open Recent menu and Favorites list always appear empty.

Solution

Apple is investigating a solution to this issue. This document will be updated as more information becomes available.

Macintosh LC, IIsi: Keys Take Place of Programmer‘s Switch

This article gives the keystroke combination that takes the place of the programmer's switch on the Macintosh LC and Macintosh IIsi.

This article has been archived and is no longer updated by Apple.
The Macintosh LC and Macintosh IIsi do not have a programmer's switch.

Here are the key combinations for the Reset and non-maskable interrupt (NMI) functions:

- Control-Command-Power generates a reset.

- Command-Power generates an NMI.

Note: MacsBug 6.2b1 or later (available from APDA) needs to be installed for the non-maskable interrupt to happen when the Command and Power keys are pressed.

These key combinations are similar to those used in the Apple IIGS.

Final Cut Pro 3 and Final Cut Express 1.x: "An error occurred finding one or more of the specified capture scratch volume(s)" Alert

When using Final Cut Pro 3 or Final Cut Express with some versions of Mac OS X, having a solidus ("/"), or "forward slash character" in clip or pathnames can set scratch disk paths to invalid locations, causing unexpected behavior during capture.
This article has been archived and is no longer updated by Apple.

Symptom

An alert box with this message appears:

> "An error occurred finding one or more of the specified capture scratch volume(s). Verify that both audio and video scratch disks are set in the Preferences."

Figure 1 Final Cut Pro alert box

Solution

For Mac OS X 10.2
Update to Mac OS X 10.2.3 or later. Use the Software Update preferences or search at the Apple Downloads page (**http://www.info.apple.com/support/downloads.html**).

For Mac OS X 10.3
Do one of the following:

- Upgrade to Final Cut Pro 4 or Final Cut Express 2.
- Avoid using the solidus in clip names, or any part of the path to the clip including the hard drive name. If you have already tried to capture a clip with a solidus in the name and the alert box above appeared, you should delete it from the clip name and capture the clip again.

  If you are using Cinema Tools for Final Cut Pro, you should also ensure that your telecine logs do not contain a solidus in clip names. You may want to use a word processor to replace all occurrences of "/" with another character such as "-". TextEdit, which comes with Mac OS X, can help you do this.

iCal 1.0: How to Go to Any Date

This document gives two shortcuts for going to any date.
This article has been archived and is no longer updated by Apple.
To go to a date that falls within a few months of the current date:

1. Click the triangles in the mini-month list to see a few months ahead.
2. Click the date in the mini-month.

To go to any date, particularly those that are more than a few months away, follow these steps:

1. Choose New Event from the File menu.
2. Change the year or month in the "from" field to the year or month you want to go to using the arrows.

The iCal window displays that year or month. From here, you can choose any day in that month from the mini-month calendar on the left.

Mac OS X 10.2, iTunes 3: CD Burning at High Speed Fails

With Mac OS X 10.2, burning an audio CD or MP3 CD using iTunes 3 may fail if you burn at a high speed (such as 24x).
This article has been archived and is no longer updated by Apple.

Symptom

Burning an audio CD or MP3 CD fails when you burn at a high speed.

Solution

Update to Mac OS X 10.2.1 or later. You may use the Software Update pane of System Preferences to update your software, or download the update from Apple Software Downloads (http://www.apple.com/swupdates/).

QuickTime 6 for Windows: Multiple Alert Boxes With the Same Message Appear

This document describes an issue that can occur if a non-Admin user deletes the QuickTime preference file.
This article has been archived and is no longer updated by Apple.

Symptom

- Multiple alert boxes with the same message appear.
- QuickTime Player stops responding.

Solution

1. Log in to Windows as an Admin user.
2. Open QuickTime Player. The preference file is recreated, which should resolve the issue.

iDVD 2.1: Slideshow Project Does Not Burn on First Try

When you burn a DVD-R that contains a slideshow, the disc may not burn on the first try.
This article has been archived and is no longer updated by Apple.

Symptom

When you burn an iDVD project that contains a slideshow:

- the burn process stops at Step 2.
- the DVD-R disc, which is still blank, is ejected.
- a prompt tells you to insert a blank disc.
- the pointer turns into a spinning disc.

Solution

After iDVD ejects the blank disc, wait a few minutes for the spinning disc to turn back into a pointer. Then, reinsert the disc you were using. iDVD should complete the burn this time.

Macintosh Classic: RAM Upgrades and 1MB Memory Expansion Card

How do I upgrade the RAM in my Macintosh Classic? What are the possible configurations and do I have to use the 1MB Memory Expansion Card?

This article has been archived and is no longer updated by Apple.
With the Macintosh Classic, Apple introduced a new memory expansion module called the Macintosh Classic 1MB Memory Expansion Card. This card is necessary to add additional RAM to a Macintosh Classic. A 2MB Macintosh Classic comes with this card installed.

Apple's memory expansion card has 1MB of memory soldered on. In addition, it carries two SIMM sockets to allow expansion with 150ns (or faster) 256K or 1MB SIMM strips (Macintosh Plus or Macintosh SE SIMMs or better). Both SIMMs must be populated at the same time with the same size RAM SIMMs in both sockets. Either low- or high-profile SIMMs can be used. A jumper must be changed if the SIMM sockets are used. You cannot use 4MB RAM SIMMs.

The following are valid memory configurations:

1 MB - Using 1MB on main logic board (MLB) only
2 MB - 1MB on MLB plus 1MB memory expansion card with no SIMMs
2.5 MB - 1MB on MLB plus 1MB memory expansion card with two 256K SIMMs
4 MB - 1MB on MLB plus a 1MB memory expansion card with two 1MB SIMMs

As with the Macintosh Plus and SE, the Classic's system memory can be extended only to 4MB. In the memory map, after the 4MB RAM space, there is the system ROM.

Macintosh LC: Expansion Slot

This article is about the Macintosh LC's PDS (processor-direct slot) expansion slot.

This article has been archived and is no longer updated by Apple.
You can expand the Macintosh LC via a 96-pin expansion connector located on the main logic board. This is Apple's first 68020 PDS, requiring a new slot definition. Expansion cards will be approximately 3-inches by 7-inches in size and will lie horizontally above the logic board within the Macintosh LC. An opening in the back of the Macintosh LC accommodates a connector the size of a DB-15. The expansion connector is supplied with the following voltages, and must be limited to the following current load:

Voltage	Current
+5	800 mA
-5	20 mA
+12	200 mA

Power limitations allow dissipation of no more than 4 watts, all of which can be taken from +5, or from any combination of the three voltages -- but the total cannot exceed 4 watts.

Here are the pinouts for the Macintosh LC PDS connector for columns A, B, and C:

TA44715_Macintosh_LC_Video_Timing_(TIL06179).pdf

Macintosh LC: Video Timing

This article gives the video timing modes for the Macintosh LC.

This article has been archived and is no longer updated by Apple.
The Macintosh LC supports 3 different timing modes:

- Macintosh 12-inch RGB Display's 512x384
- Macintosh 12-inch RGB Display's 560x384 (generated by Apple IIe card, 4-bit only)
- Macintosh 12-inch Monochrome Display, Macintosh High-Resolution Monochrome, Macintosh High-Resolution RGB (640x480)

In 640x480 mode, Macintosh LC uses the CPU clock (31.3344 MHz) as the pixel clock. This is opposed to the 30.24 MHz clock that is normally specified. This results in 32 extra pixels per scan line. The 640 active pixels are centered in the active video field with 16 black pixels placed on either side. Horizontal and vertical scan rates remain the same. A visual distortion from square pixels will occur, making the pixels 3% too narrow. The Macintosh 12-inch Monochrome display will be able to correct for this distortion, but the current monochrome and RGB monitors will not.

The 560x384x4 Apple IIe mode is selectable only when an Apple IIe card is present. The card is necessary because the 17.234 MHz oscillator required for this video mode is located on the Apple IIe card itself.

iMovie 3.0: Dragging MP3 File From Audio Pane to Desktop Moves the Original File

If you drag an MP3 file from the Audio pane to the desktop, the original file is moved to the desktop.
This article has been archived and is no longer updated by Apple.

Symptom

When you drag an MP3 file from the Audio pane to the desktop, the original file is moved to the desktop. iTunes no longer recognizes where the song is located.

Solution

1. Double-click the MP3 file to re-add it to the iTunes Music Library.
2. Drag the file back to the iTunes Music folder in your Home (~/Music/iTunes/iTunes Music). Note: The iTunes Music folder may be in your Documents folder.

Published Date: Feb 18, 2012

Installing iPod Software 2.0 for Windows

Before you install
This article has been archived and is no longer updated by Apple.
The entire installation process can take up to 20 minutes to complete.

Bringing any other windows or applications in front of the Installer windows may confuse the Installer, causing it to always present the Installer windows behind all other applications and windows, or make pop-up menu selections in the Installer window work incorrectly. If this happens, double-click the Back button twice, then click the Next button to refresh the Installer window.

If at any time a dialog appears asking to install a driver for the iPod's hard disk, dismiss it and do not click OK.

How to install

1. Insert the CD into the computer's disc drive.
2. After a short wait, the Choose Setup Language window appears, shown here.

If the installer does not open automatically:
   1. Open My Computer.
   2. Open the CD.
   3. Double-click the "setup" install icon, shown here.

3. The configuration progress bar appears, shown here.

4. When the iPod for Windows V2.0 window appears, click Install, as shown here.

5. The iPod Serial Number dialog box appears. Type in iPod's serial number, as shown here. The serial number is engraved on iPod's metal case.

Tip: Enter an 11-character iPod serial number to enable the Next button.

The serial number is also available in iPod's menu system.

6. Click Next. The Software License Agreement window appears, shown here. Read the text. If you agree, click Yes.

7. Select your country or region and click Next, as shown here.

8. If your country is not shown, select Show All to reveal other choices.

9. Click Next. When Registration Information appears, fill out the appropriate information and click Next.

10. Fill in the registration window, then click Next.

11. The "iPod needs to be configured" message appears. This message will appear even if an iPod is not connected to the computer, or if the iPod has already been formatted for Windows.

If iPod has already been configured for use with Windows, click Cancel. You can always run the iPod Software Updater at a later time to convert iPod for use with Windows.

If iPod has not been configured for use with Windows, click the OK button. This will restore iPod from within the Installer. This process can take several minutes. (The iPod Software Updater does not open.) **Warning:** This erases iPod and changes its format to FAT32. All data on iPod will be lost.

12. After many installation windows appear and disappear, the Choose Destination Location window appears. Click Next. When the Choose Destination Location window appears, click Next to accept the default location (C:\\Program Files\\iPod).

Important: iPod for Windows software must be installed on the C drive. If it is not, when you restart the computer an alert with this message will appear, "The iPod Watcher did not load due to an error."

13. There is about a two-minute delay while iPod for Windows installs, many windows will appear and disappear during this process:

14. The iPod for Windows User Guide 2.0 installer automatically opens and installs with no user interaction.
15. The MUSICMATCH Jukebox installer automatically opens.

Old HD-20 and New Macintosh SE/30

What must one do to access a (non-SCSI) HD20 disk drive attached to the disk drive port on the new Macintosh SE/30? I tried placing the old "HD20" file in the System Folder, but it didn't work.

This article has been archived and is no longer updated by Apple.
Using the criteria of "Macintosh SE/30 AND NON-SCSI" search AppleLink's Technical Info library for the article "Macintosh SE/30: Doesn't Work with an Apple Hard Disk 20." The following is more information on this subject:

The (non-SCSI) Hard Disk 20 does not work with the Macintosh SE/30. The Macintosh SE/30 has the same logic board and ROM as the Macintosh IIx, which does not support the Hard Disk 20. Therefore, the code to support the drive is not included in the ROM of the Macintosh SE/30.

There are ways of retrieving the data from a Hard Disk 20 for use on the Macintosh SE/30. First, using a Macintosh Plus or Macintosh SE, transfer the data to another hard disk that the Macintosh SE/30 can read. The necessary equipment and steps to do this are:

To transfer data from a Hard Disk 20 to the internal drive, these items are required:

- Macintosh Plus or Macintosh SE

- Formatted, blank HD20 SC, HD40 SC, or HD80 SC and cables

- System 6.0.3 Tools Disk (included with the Macintosh SE/30)

Once you have the necessary items, follow these steps:

1) Hook up the Hard Disk 20 and the HD20 SC, HD40 SC, or HD80 SC to the Macintosh Plus or Macintosh SE.

2) Insert the System Tools disk in the internal drive.

3) Turn on both drives, wait 10 seconds, and then turn on the computer.

4) Use the Find File DA and look for a file called System on the Hard Disk 20.

5) There should be one file called System, and it should be located in the System Folder. If there is more than one System file, return to the desktop and trash the other System files on the Hard Disk 20.

6) Select all the files and folders on the Hard Disk 20 and any files that may be on the desktop and drag them to the HD20 SC, HD40 SC, or HD80 SC.

7) After the copy is finished, hook up the HD20 SC, HD40 SC, or HD80 SC to the Macintosh SE/30.

8) Select the files from the HD20 SC, HD40 SC, or HD80 SC and drag them to the internal hard drive. If there is no internal hard drive, drag them to the drive you will be using.

9) Update the System files to System 6.0.3 using the Installer Script (located on the System Tools Disk) for the Macintosh SE/30.

Additionally, we have included an INIT Utility that reads the data from the Hard Disk 20 and puts it on the internal hard disk of the Macintosh SE/30. As with all INITs, place it in the System Folder of the startup disk. The Hard

Disk 20 will now be visible when you start up with the Hard Disk 20 turned on.

Warning: Do not try to write to the Hard Disk 20. Trying this can result in the loss or corruption of data on the Hard Disk 20.

When the Hard Disk 20 icon is visible, you can drag the files from the Hard Disk 20 onto the internal hard disk of your Macintosh SE/30.

The code for the INIT Utility is not supported by Engineering, and no changes will be made to it. Be very careful when using this Utility and do not distribute it. Once you have copied the Hard Disk 20 to your Macintosh SE/30, be sure to remove this Utility from your System Folder.

Keynote 1.0: About Making Text Italics or Bold

This document describes issues using italic or bold text with some themes in Keynote.

This article has been archived and is no longer updated by Apple.

Some Keynote themes use fonts that are not available in italics or bold typeface versions. If you want to change your font to one that can be italicized or made bold, choose Format > Font > Show Fonts. In the Fonts window, select a font in the Family column. Available typefaces appear in the Typeface column.

Keynote 1.0: Tables and Charts in QuickTime Export Are Partly Covered With White or Are Fragmented

If tables or charts are partly covered with white or appear fragmented when you export to QuickTime, try exporting the slideshow again.
This article has been archived and is no longer updated by Apple.

Symptom

When you export a slideshow to a QuickTime movie, tables and charts are partly covered with white, or appear fragmented.

Solution

Try exporting the slideshow again. The tables and charts should appear properly in the second export.

A/UX 2.0 and Native X11: Frequently Asked Questions

This article contains frequently asked questions (FAQ) about A/UX 2.0 and Native X11.

This article has been archived and is no longer updated by Apple.

Question: Can you configure "native" X11 to use an "azerty" keyboard?

Answer: On an "xterm" window, we think that the X client application called "xmodmap", a keyboard modifier utility for X, could be used to alter the X keyboard map and key symbol table. For example, on a standard Apple Macintosh keyboard, to change the capital letter "A" to a capital letter "Q", you would use the command: xmodmap -e "keycode 20 = A".

For more details, please see the xmodmap (1) manual pages.

Question: How can I configure "native" X11 to have a 24-bit display?

Answer: The current distributed Macintosh A/UX "native" X server, which is based on X11R4, supports only 1-bit (monochrome) and 8-bit (8 bits per pixel, 256 colors) displays.

Keynote 1.0: Bulleted Text Was Deleted When You Exported

Bulleted text may be deleted when you export a slideshow to PowerPoint.
This article has been archived and is no longer updated by Apple.

Symptom

Bulleted text is deleted when you export a slideshow to PowerPoint.

Solution

Because Microsoft PowerPoint and Keynote deal differently with bulleted text, some bulleted text items may be lost when you export a Keynote document to PowerPoint. If you hide the bulleted text on a slide (by deselecting the Show Body checkbox in the Slide Inspector), it will be deleted from the outline when you export.

Keynote 1.0: Too Much Space Between Lines of Text

Install the Mac OS X 10.2.3 update if the text of slides imported from PowerPoint is too far apart.
This article has been archived and is no longer updated by Apple.

Symptom

There is too much space between lines of text on slides you imported from PowerPoint--even when the line spacing is set to 0. You can't set the line spacing to a negative value.

Solution

Install the Mac OS X 10.2.3 update. It is available from the Software Update pane of System Preferences, or from the Apple Software Downloads website (http://www.apple.com/swupdates/).
Published Date: Feb 18, 2012

Keynote 1.0: Double-Clicking Chart Doesn‘t Do Anything

To edit a chart, click the Chart icon in the toolbar.
This article has been archived and is no longer updated by Apple.

Symptom

Double-clicking a chart doesn't do anything.

Solution

Clicking more than once on a chart selects various subregions of the chart (columns, text, and so forth). To edit a chart, click the Chart icon in the toolbar.

Keynote 1.0: QuickTime Movie Begins Playing Immediately

QuickTime movies you place in a slide begin playing immediately during a presentation.
This article has been archived and is no longer updated by Apple.

Symptom

QuickTime movies you place in a slide begin playing immediately during a presentation. The User's Guide states that the poster frame displays until "you start the movie." However, you can't start the movie. It simply starts by itself.

Solution

You can delay starting a movie if you make the movie "build in". Assign it a build type and order in the Build Inspector.
Published Date: Feb 18, 2012

A/UX 2.0: "apropos dt"

"apropos dt" yields nine occurrences of the line "Mon Apr 23 xx:xx:xx PDT 1990". This is a minor annoyance, but why does it happen?

This article has been archived and is no longer updated by Apple.

The repeated time-stamped "Mon Apr 23 xx:xx:xx PDT 1990" lines displayed with the "apropos dt" command are caused by the /usr/lib/whatis database file. The "apropos dt" displays any line matched with the "dt" string (not case sensitive) from the /usr/lib/whatis file. The workaround to this minor annoyance is to remove these time stamp lines from the /usr/lib/whatis file.

Final Cut Express: How to Capture From Non-Controllable Device

Learn how to capture from non-controllable devices such as analog-to-DV converters in Final Cut Express.
This article has been archived and is no longer updated by Apple.
Final Cut Express versions 1.0.1 and later can capture from non-controllable devices using the following steps:

1. From the **Final Cut Express** menu, choose **Easy Setup**.
2. From the **Setup For** pop-up menu, choose either **DV-NTSC DV Converter** or **DV-PAL DV Converter** depending on whether you're working with NTSC or PAL material.
3. From the **File** menu, choose **Capture**.
4. Cue your footage to at least five seconds before the desired recording point, and press play on the camera or deck.
5. Click the Now button in the Capture area of the Capture window. This button is in the lower-right area.
6. When done recording, press the Esc (Escape) key on your keyboard.

If you are using Final Cut Express 1.0, then **update** to Final Cut Express 1.0.1 or later to obtain this feature.

Final Cut Express 1.0: Imported iMovie 3 Projects Don‘t Include Adjusted Volume

iMovie allows you to adjust the volume of a clip by using a volume slider in the main window. However, after importing an iMovie project whose volume has been adjusted into Final Cut Express, the clip volume remains at its original level.
This article has been archived and is no longer updated by Apple.

Symptom

iMovie 3 projects imported into Final Cut Express use the volume of the clips as originally captured from the camera or video device.

Solution

Use the audio tools in Final Cut Express to adjust the volume to its desired level.
Published Date: Feb 18, 2012

Final Cut Express 1.0: Extracted Audio From iMovie Projects Contains Original Files

Projects imported from iMovie where the audio has been extracted and changed contain audio tracks for both the original audio and the changes to the extracted audio. For example, an iMovie project with extracted audio that has been deleted in iMovie will still have the original audio in Final Cut Express.

This article has been archived and is no longer updated by Apple.

Symptom

Changes to extracted audio in iMovie are not reflected in Final Cut Express

Solution

Make the desired changes to the audio tracks from within Final Cut Express.

A/UX 3.0: Configuring sendmail (10/95)

I have some problems using mail on TCP/IP with A/UX 3.0.

I can receive messages, but I can't send them. When I use "mailq" to see the messages in the queue, I see: "Deferred: Host Name Lookup Failure" for all messages I tried to send. I haven't modified the mail configuration files. I just wrote the name of the remote host on "/etc/hosts" to use on the mail command. I know the connection works fine on the host supporting A/UX because I can use Telnet, ftp, and so on.

Can you help?

This article has been archived and is no longer updated by Apple.
As shipped, A/UX 3.0 works only with local mail. To get either UUCP or network mail working, you need to reconfigure the /usr/lib/sendmail.cf file. To use the TCP/IP-based (Ethernet) mail, you must have a nameserver running on the network.

NOTE: With A/UX 3.1 these changes are not necessary.

If a fully qualified domain name is the only form of mail address that a user on the computer will generate, modify the file /usr/lib/sendmail.conf/cf/aux.mc so that it contains your Internet domain name. Here is the line to change, as installed from the standard A/UX distribution:

define(DOMAIN, 'DDaux.apple.com')

Change aux.apple.com to your Internet domain name as specified in the /etc/resolv.conf file.

After modifying aux.mc, enter this sequence of commands to make a new sendmail configuration file:

cd /usr/lib/sendmail.conf/cf

make aux.cf

The result of the make command is a file called aux.cf. Move aux.cf to the configuration filename that sendmail uses, by entering this command:

mv aux.cf /usr/lib/sendmail.cf

Now startup sendmail by typing:

/usr/lib/sendmail -bd -q30m

The -bd option causes sendmail to run as a daemon. The -q30m option causes sendmail to process the local mail queue every 30 minutes.

Refer to the A/UX Network System Administration manual chapter on Setting Up Network Mail for further details.

Article Change History:
16 Oct 1995 - Changed title to reflect A/UX 3.0, and added A/UX 3.1.
12 Sep 1994 - Updated for A/UX 3.0.
31 Aug 1992 - Reviewed.

Final Cut Express 1.0: Before You Install

This document outlines the system requirements for Final Cut Pro Express 1.0.
This article has been archived and is no longer updated by Apple.

System Requirements

You'll need the following equipment for Final Cut Express 1.0:

One of the following computers:

- Power Macintosh G3/300 megahertz (MHz) or faster with built-in FireWire
- Powerbook G3/400 MHz or faster with built-in FireWire
- iMac 350 MHz or faster with built-in FireWire
- iBook (Dual USB) 500 MHz or faster with built-in FireWire
- eMac
- Xserve

Hardware and video equipment:

- A CD or DVD drive
- 256 MB RAM (384 MB or greater required for G4 Real-Time editing)
- A 6 GB, Audio/Video rated disk driver (20 GB or greater recommended)
- Dual monitor support (optional)
- The correct FireWire or device control cable and any additional cables you may need for connecting your deck or camcorder to your computer
- A DV (digital video) source, such as a camcorder or deck connected to your computer via a FireWire port (FireWire is also referred to as IEEE 1394 or Sony iLink.)

Note: G4 Real-Time editing requires a single or dual processor Power Macintosh G4 500 MHz or faster computer (PowerBook G4 667 MHz or faster recommended for real-time mobile DV editing).

Software:

- Mac OS X 10.2.2 or later
- QuickTime 6.0.2 or later

Final Cut Express 1.0: Late-Breaking News

This document contains important late-breaking information about Final Cut Express.
This article has been archived and is no longer updated by Apple.
This document contains important late-breaking information about Final Cut Express. For the latest information about product updates, tips and techniques, and qualified third-party devices, visit the Final Cut Express website (http://www.apple.com/finalcutexpress/).

iDVD Chapter Marker Limit
iDVD has a chapter marker limit of 36 chapters. If you have assigned more than 36 chapter markers to your movie in Final Cut Express, it will not open in iDVD.

Final Cut Pro Project Files May Not Be Opened by Final Cut Express
Project files created using Final Cut Pro are not supported in Final Cut Express. However, project files created in Final Cut Express may be opened in Final Cut Pro.

Opening an iMovie Project in Final Cut Express
You can open and edit movies created in iMovie with Final Cut Express. To open an iMovie project, follow these steps:

1. In Final Cut Express, choose Open from the File menu.
2. In the dialog that appears, select the iMovie project you want to open. The iMovie project opens in the Browser and contains the sequence and clips as they appeared in the iMovie clips shelf.
3. Double-click the sequence to open the iMovie project in the Timeline.]
4. Render the sequence.

About iMovie DV Files
Imported clips are linked to the original clips captured in iMovie (found in your iMovie projects Media folder). These clips are iMovie DV files and are encoded differently from the QuickTime files Final Cut Express captures.

- DV Stream files do not have timecode tracks, so media imported from iMovie project files cannot be recaptured. All imported source media must be preserved for future reediting.
- Imported iMovie DV files may not play back or Print to Tape in real time without being rendered.

Important: Final Cut Express does not import iMovie sound effects, titles, and transitions. Only applied effects are imported. Importing project files from iMovie 2 or earlier may result in one large clip.

Keynote 1.0: Stops Responding During Slide Show

Keynote 1.0 may stop responding or unexpectedly quit during a slide show presentation.
This article has been archived and is no longer updated by Apple.

Symptom

Keynote stops responding or unexpectedly quits during a slide show presentation.

This issue has been reported most often when using 500 MHz iBook computers with Mac OS X10.2.3, but other models may be affected.

Solution

Update to Mac OS X 10.2.4. Information on how to update to Mac OS X 10.2.4 is available in technical document 107362 "**Mac OS X: About the Mac OS X 10.2.4 Update**."

Published Date: Feb 18, 2012

Final Cut Express 1.0: Unexpectedly Quits While Opening

Final Cut Express can unexpectedly quit when opening if effects windows are open in icon view.
This article has been archived and is no longer updated by Apple.

Symptom

When you try to open Final Cut Express, an alert with this message appears:

> "The application Final Cut Express has unexpectedly quit."

Solution

Delete the Final Cut Express 1.0 Prefs file so that the application can open normally. The file is located at the following path in your home folder: ~/Library/Preferences/Final Cut Express User Data/Final Cut Express 1.0 Prefs

The application should now open and work normally.

To prevent the issue from happening again, update to Final Cut Express 1.0.1.

Keynote 1.0: Imported Slideshows Are Slow on Certain Slides

You may need to group graphic elements before importing them into Keynote.
This article has been archived and is no longer updated by Apple.

Symptom

Some slides from an imported slideshow seem particularly slow when you view them. They contain many graphic elements.

Solution

Group the graphic elements before importing the slideshow in Keynote.
Published Date: Feb 18, 2012

Keynote 1.0: Conflict With Some Versions of "Default Folder" Utility

Earlier versions of the utility "Default Folder" may cause Keynote to unexpectedly quit.
This article has been archived and is no longer updated by Apple.

Symptom

After placing a movie or sound file in a Keynote presentation file, the application unexpectedly quits.

Solution

Check to see if the utility "Default Folder" is present in System Preferences. To resolve the issue, update to a later version of Default Folder, or disable the utility by turning it off from the Default Folder preference pane.

Default Folder is available from the St. Clair Software website (http://www.stclairsw.com/).

Keynote 1.0: Slides Play Slowly When "Scale slides up to fit monitor" Option Is On

If slides play slowly after you turn on the "Scale slides up to fit monitor" option, decrease the display resolution instead.
This article has been archived and is no longer updated by Apple.

Symptom

Slides play slowly after you turn on the "Scale slides up to fit monitor" option in Keynote Preferences. This seems to particularly affect slides with charts and chart builds.

Solution

1. Open Keynote.
2. Choose Keynote > Preferences.
3. Deselect the "Scale slides up to fit monitor" option.
4. Click Open Display Preferences.
5. Choose a smaller screen resolution.

Published Date: Feb 18, 2012

DVD Studio Pro 1: Does Not Create Images for 80 mm DVD-Video Discs

DVD Studio Pro 1.0 and later does not have a feature to create images for the 80 mm DVD-Video disc format.

This article has been archived and is no longer updated by Apple.

DVD Studio Pro does not have a feature to create images for the 80 mm DVD-Video disc format. DVD Studio Pro outputs images suitable for 120 mm discs only. Many consumer DVD players cannot properly play 80 mm DVDs unless the size is explicitly set in the authoring software.

A/UX: Frequently Asked Questions (11/95)

This article contains frequently asked questions (FAQ) about A/UX?

This article has been archived and is no longer updated by Apple.
Question: Do customers get the source code for A/UX and X Windows?

Answer: No, the source code is not included in the normal distribution of A/UX and X Windows System. However, it will be available from APDA on special request when released. As far as we know, the source for the current release of A/UX 3.0 has not been made available to APDA. The information for source won't be listed on the APDA catalog since it is a special request item and it requires lots of "License Agreement Signatures".

Question: Does the TCP/IP implementation follow "Host requirements (RFC 1122 and 1123)"?

Answer: According to A/UX Network Engineering, A/UX 3.0 TCP/IP implementation does follow the RFC 1122 and RFC 1123 (Host requirements).

Question: Does the NFS implementation have the same functionality as SunOS 4?

Answer: The NFS implementation under A/UX runs the same NFS version (protocol release 2.0 and implementation source 3.2) as SunOS 4.0.x does. However, the "mount daemon" feature (which is supported in SunOS 4.0.x) is not included.

Question: Can you give quota restrictions on users over NFS?

Answer: No disk quota on users is implemented under the A/UX Berkeley file system.

Question: What backup system do you recommend?

Answer: A/UX supports Apple Tape Backup 40SC. You can also use Dantz
Retrospect and any backup media they support.

Question: Is the X Window System 11.3 or 11.4 (I have read that some parts are 11.4)?

Answer: The current release of X Window System for A/UX 3.0 is based on 11R4.

Question: Do the GNU products run on A/UX (GNU-EMACs, gcc, g++)?

Answer: We have heard that some people on the network have run GNU products on A/UX.

Question: Do the "cdb" and "adb" debugging programs have the same functionality as "dbx"?

Answer: "cdb" and "xdb" are third-party products. We haven't tried them nor compared their functionality. However, we know that "cdb" is an interactive, source-level debugger for C and assembly-language programs, and it supports programs generated from the C compiler included with A/UXor from third-party compilers that generate Common Object File format symbol tables.

Question: Is the C implementation compliant with ANSI X3J13?

Answer: The A/UX C compiler is not compliant with ANSI X3J13.

Question: Is there a C++ (AT&T Cfront 2.0)?

Answer: Try Oasys's C++.

Question: Is there a Pascal compiler (compliant with the ISO-standard)?

Answer: This is not supported by Apple. Look for third-party solutions.

Question: Is there a Cross assembler for MC68020 systems?

Answer: This is not supported by Apple. Look for third-party solutions.

Question: Is the ADA cross compiler compliant with ANSI-83?

Answer: This is not supported by Apple. Look for third-party solutions.

Question: Is there a system for delaying execution of processes to a later time (some sort of "batch system")?

Answer: The "cron" or "at" under A/UX allows you to schedule tasks for later time.

Question: Are there tools for distributed programming (similar to SUN ONC or Apollo NCA)?

Answer: This is not supported by Apple. Look for third-party solutions.

A/UX 2.0: Troubleshooting AppleShare File Server Access Problem

I have A/UX 2.0 running on a Macintosh IIx with 5MB RAM and an HD160 SC. I can access the LaserWriters on the network easily from the Chooser and CommandShell, but I'm having a problem accessing the file servers. I am using a LocalTalk-only connection. The file servers appear in the services window on the right side of the Chooser window just as they do while I'm in Macintosh OS, and I can mount those servers while in Macintosh OS.

I noticed that the bottom right area of the Chooser window did not have the normal text/buttons included--"AppleTalk; ON; OFF". When I try to mount the file servers while in A/UX, the system shows the watch cursor and gives this alert message: "No response from server. Please try again."

Can you help?

This article has been archived and is no longer updated by Apple.

Unfortunately, we can't reproduce this symptom. We are running AppleTalk via a LocalTalk-only connection without any problem. Both printing and AppleShare services work properly.

It sounds strange that you can access the LaserWriter but not the AppleShare server on the AppleTalk network.

When an AppleShare server is selected, the bottom right area of the Chooser window should show an "OK" button and a "User Name" input dialog box. We don't see the "AppleTalk; ON; OFF" text in the window.

Here are some areas to check:

- Is the server you tried to mount up and running? Did you get the same "No response from server ..." message when you select another server?

- Is the Apple Internet Router running AppleTalk Phase 2?

- Make sure that the default port for AppleTalk via LocalTalk is the printer port (tty1), which must be set with the getty disabled.

- Make sure that the "interface = localtalk0" line in /etc/appletalkrc is set.

- When AppleTalk is shutdown via "appleTalk -d" and you try to bring it up again, the Mac 32 environment needs to be run again to make AppleTalk effective again. This can be done using the "Logout" and "mac32; screenrestore" sequences or by restarting the system.

- Use "appleTalk -s" to see the AppleTalk status.

iMovie 3 stops responding during effect preview

In Mac OS X 10.1.5, choosing a menu item while iMovie previews an effect, transition, or title may cause the application to stop responding or unexpectedly quit.
This article has been archived and is no longer updated by Apple.
This issue does not occur with Mac OS X 10.2 or later.

Tip: Wait for the preview to finish before choosing a menu item.
Published Date: Feb 18, 2012

iMovie 3: How to Switch From NTSC to PAL

iMovie initially set all projects to PAL or NTSC video depending on the type of camcorder or device you connect to the computer, or the format of the first video you import.
This article has been archived and is no longer updated by Apple.
To set new projects to be NTSC or PAL, follow these steps:

1. Update to iMovie 3.0.3 or later. It is available from the iMovie website (http://www.apple.com/imovie/). iMovie 4 is available as part of iLife (http://www.apple.com/ilife).
2. Open iMovie.
3. From the **iMovie** menu, choose **Preferences**.
4. Change "New Projects are:" to either NTSC or PAL.

Published Date: Feb 18, 2012

iMovie 3: How to Export to iDVD 2

This document explains how to export footage from iMovie 3 to iDVD 2.
This article has been archived and is no longer updated by Apple.
Follow these steps to export iMovie 3 projects to iDVD 2:

1. From the **File** menu, choose **Export**.
2. From the **Export** pop-up menu, choose "**To QuickTime**".
3. From the **Formats** pop-up menu, choose "**Full Quality DV**".
4. Click Export.
5. Type a name for the exported movie and click Save.

Place the exported movie file into your iDVD 2 project.

Note: Chapter markers are not a feature of iDVD 2. To export chapter markers from iMovie 3 to an iDVD project, use iDVD 3.

MacX and xgif: Why Color Table Change Causes Slow Display

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

Why is MacX so slow when a client changes the color table? The change of a single table entry seems to cause a substantial delay in the displayed pixel and is accompanied by some strange color changes in the current table (for example, color flashes).

What is the problem? Is there a way around this so that the display update is as clean and fast as the stand-alone X11 server?

This article has been archived and is no longer updated by Apple.
The problem that you are experiencing is most likely due to the way the X client application uses the Color Lookup Map. We have seen a difference between the two versions of the xgif program. The old version of xgif (which uses the default colormap) causes the most slowness. The new version (which uses the colormap routine in the Xlib) behaves much faster. Here are examples of C code used by the two versions of xgif:

Old version:
```
#define DefaultColormap(pty, scr) (((dpy)->screens[(scr)]).cmap)
theCmap = DefaultColormap(theDisp, theScreen);
```

New version:
```
theCmap = XCreateColormap(theDisp, rootW, theVisual, AllocNone);
```

We also experienced similar effects (color flashing and/or changing) on the Native X11 server.

Final Cut Express 1.0.1: Device Control Settings Dialog Appears In Localized Versions

When you first open Final Cut Express, an option to choose a device preset appears. In the localized (Japanese, French, German) versions of the application, if you choose the DV Converter preset then you also see an option to select Device Control Settings. If the incorrect device control setting is chosen, the program will not be able to capture from a DV converter.
This article has been archived and is no longer updated by Apple.

Symptom

- An unexpected dialog appears when you first open a localized version of Final Cut Express.

  or
- You are unable to capture from a DV converter device with a localized version of Final Cut Express.

Solution

Be sure to choose Non-Controllable Device in the Device Control Settings window. See Figure 1.

Figure 1 Japanese version of the Device Control Settings window

Follow these steps If you already selected a different setting and cannot capture from a DV converter:

1. If the application is open, choose Final Cut Express > Quit.
2. Click the Finder icon in the Dock.
3. Choose Go > "Go to Folder".
4. Type: ~/Library/Preferences/
5. Click Go.
6. Drag the folder named "Final Cut Express User Data" to the Trash.
7. Open Final Cut Express.
8. Choose the desired preset, and if asked, choose Non-Controllable Device from the pop-up menu. If you see a dialog stating "Unable to locate the external video device...", click "Continue" to proceed.

iPod For Windows 1.2.6: Only Apple Logo Appears When Restoring Over iPod for Macintosh

Your iPod may "freeze" only displaying an Apple logo if it is an early iPod for Macintosh model and you restore it using iPod for Windows 1.2.6 software. This document explains how to return your iPod to working condition.
This article has been archived and is no longer updated by Apple.

Symptom

Your iPod for Macintosh "freezes" only displaying an Apple logo after you restore it using iPod for Windows 1.2.6 software.

Note: Reformatting your iPod for Macintosh to work with Windows is an unsupported operation.

Solution

1. Reset your iPod and force it into FireWire mode. See technical document 61584, "**iPod: Only Apple Logo Appears When You Turn on iPod**" for instructions.
2. Restore iPod using the software that was included with it (iPod software 1.2.2 or earlier).
3. Reset iPod. See technical document 61705, "**iPod: How to Reset**" for steps to reset your iPod. Note that iPod will continue to appear not to work until it restarts.
4. Update to iPod 1.2.6 for Macintosh.

iPod 2.0: MusicMatch Doesn‘t Open When You Connect iPod to Your Computer

MusicMatch does not open automatically when you connect iPod to your PC. iPod does appear under Attached Portable Devices in MusicMatch when you open MusicMatch manually.
This article has been archived and is no longer updated by Apple.

Symptom

MusicMatch does not open automatically when you connect iPod to your PC. iPod does appear under Attached Portable Devices in MusicMatch when you open MusicMatch manually.

Solution

1. Connect iPod to the computer.
2. Choose iPod Manager in the Start Menu.
3. Click the Change Home Application button.
4. Click the disclosure triangle in the Select Home Application window.
5. Choose MusicMatch JukeBox from the list.
6. Click OK.
7. Close iPod Manager.

TA44762_Super_Serial_Card_Manual_Errata__(TIL00619).pdf

Super Serial Card: Manual Errata (12/96)

Listed below are corrections to the Super Serial Card Owner's manual.

This article has been archived and is no longer updated by Apple.

Page 5

The second paragraph under "Preparing the SSC for Printer Mode" should read:

If the triangle on the jumper is pointing toward the word "Modem", remove the block, using an IC Extractor if necessary, then carefully reinsert it so the triangle is pointing towards the word "Terminal"."

Page 13

The example for Applesoft BASIC should read:

Applesoft BASIC: Print CHR$(9); "command"

Page 21

The second paragraph under "Preparing the SSC for Communication Mode" should read:

If the triangle on the jumper is pointing down toward the word "Terminal", remove the block, using an IC Extractor if necessary, then carefully reinsert it so the triangle is pointing toward the word "Modem"."

Page 36

The last two lines of the paragraph titled "A Terminal Mode Example" should read:

"...BASIC program to an Applesoft program, substitute CHR$(4) for D$, and CHR$(1) for A$. Leave out program lines 40 and 42."

Page 54

In the section that starts "$C08A+s0 Command", bit 1 of the Command Register should be set to 0 to enable the receiver to cause interrupts.

Apple GS/OS Error Messages: Where to Find Explanations

I am trying to copy files from an Apple IIGS to an Apple HD40 SC. The Apple IIGS consistently returns the error message 8020. I cannot find this error message anywhere.

1) What is the error message?
2) Where can I find a definitive article on GS/OS error messages?
This article has been archived and is no longer updated by Apple.
1) The error description is "invalid request." The programmer's constant is "DrvrBadReq". Since the error number is 8020 instead of 0020, the error is coming from the Finder, not directly from GS/OS. An error code directly from GS/OS would be in the format of "00xx". An error code passing through the Finder has the high bit set and produces a format of "80xx". Where "xx" is the actual error code.

2) Both Volume 1 and Volume 2 of the "GS/OS Reference" has an Appendix E containing the GS/OS error codes and the message related to that code. The individual system call description indicates which GS/OS errors that call may return. System Loader error messages are given within the System Loader call description section.

iPod for Windows 2.0: Basic Troubleshooting and How to Avoid Issues

This document provides basic troubleshooting steps and tips and explains how to avoid issues.
This article has been archived and is no longer updated by Apple.

How to Avoid Issues

- Install the latest updates and service packs from Microsoft.
- Watch iPod's screen. The disk activity indicator (looks like two arrow spinning in a circle) appears in the upper left corner of the screen. Before doing anything on the iPod (viewing the contents in Explorer, disconnecting, and so forth) wait for the arrows to stop spinning.
- In the installer, make sure you follow the instructions that appear on the screen. The exception is if Windows interrupts the installer and asks you to restart your computer before the iPod installer has finished.
- Setting up iPod for the first time can take some time. Be patient. Windows ME performance is not as good as with Windows XP, and can take up to 4 minutes to display the safe to disconnect message during the Configuration step.
- Before you restart your computer, remove iPod from its cradle, or eject it from the file system. See technical document 61724, "**iPod for Windows: How to Eject and Disconnect iPod From Your Computer**".

Basic Troubleshooting

When you run into an issue that you did not expect with the iPod connected to your Windows PC, you can generally resolve it by doing the following:

1. Check to make sure the cables are securely connected to the iPod and to your PC.
2. Wait until disk activity stops on your iPod. Click the disk eject button in the system tray. It has a disk icon with a green arrow pointing to the left on top of it. Select "Stop IEEE 1394 Device". Wait for the "Safe To Remove Hardware Device" message to appear and click OK. Unplug iPod then reconnect it.
3. Repeat the last step you performed on your PC before you encountered the behavior you did not expect.
4. Quit MUSICMATCH Jukebox and reopen it.
5. Restart your PC.

If you still experience issues, and the basic troubleshooting in the iPod Users Guide does not help, try restoring iPod's software.

For advanced troubleshooting steps, see technical document 61903, "**iPod for Windows 2.0: Advanced Troubleshooting**".
Published Date: Feb 18, 2012

iPod for Windows 2.0 with MusicMatch: Advanced Troubleshooting

This document outlines advanced troubleshooting steps for iPod for Windows 2.0. For basic troubleshooting steps, see technical document 61902, "**iPod for Windows 2.0: Basic Troubleshooting and How to Avoid Issues**".
This article has been archived and is no longer updated by Apple.
As shipped from the factory, iPod's hard disk is formatted as a Mac OS Extended format (HFS Plus) volume. When you connect iPod to a PC, iPod for Windows 2.0 software reformats the disk using the Windows (FAT32) format. If iPod does not appear in MusicMatch the first time you connect it after installing the software, the disk may be still formatted as a Mac OS Extended disk. You can check the disk format in the About Screen in the Settings menu. If it does not say "Windows" then reinstall the iPod software and check again to make sure it formatted the disk using the Windows (FAT32) format.

If iPod still does not appear in MusicMatch, close MusicMatch and reopen it. If iPod still does not appear, use the Windows Safe Remove feature to remove iPod, wait until disk activity stops on iPod, then disconnect and reconnect iPod.

If iPod does appear in MusicMatch, but its screen says "Do not disconnect," open iPod Manager and make sure MusicMatch Jukebox is the Home Application. If it is not, click "Change Home Application," and select "MusicMatch" from the dropdown box. Stop iPod by clicking on the disk eject icon in the system tray. (It has a disk icon with a green arrow pointing to the left on top of it.) Select "Stop IEEE 1394 Device". Wait for the "Safe To Remove Hardware Device" message to appear and click OK. Unplug iPod then reconnect it.

If iPod does appear in MusicMatch, but you see menus on iPod's screen, make sure disk mode is turned on. Click on iPod Manager in the system tray, or open it by choosing Start Menu > Programs > iPod > iPod Manager. Make sure the "Enable disk Mode" option is selected, then disconnect and reconnect iPod.

If your iPod does not appear in MusicMatch, check to make sure you can view the contents of iPod's hard disk in Windows Explorer. If you can't, reset iPod. See technical document 61705, "**iPod: How to Reset**" for instructions. If you've made sure iPod's disk is formatted for Windows (see the first step in this document), and you've made sure you have the latest updates from Microsoft installed on your computer, also make sure iPod appears in Device Manager and is working properly. (There no yellow exclamation point or red X over its icon.) If it does not, reconnect iPod, open the iPod Updater application, and follow the instructions to restore iPod to factory settings.

iPod for Windows: Delay While MusicMatch Connects to iPod

If your iPod is full, there may be a delay of a few minutes while MusicMatch connects to iPod.
This article has been archived and is no longer updated by Apple.

Symptom

iPod doesn't appear in MusicMatch until several minutes after you connect it to your computer.

This may happen more often when iPod's hard disk is full.

Solution

Wait for MusicMatch to finish scanning iPod's hard disk. This could take about 10 minutes if iPod's disk is full.

How to uninstall MUSICMATCH Jukebox

Follow these steps to uninstall MUSICMATCH Jukebox, part of iPod Software 2.0 for Windows.
This article has been archived and is no longer updated by Apple.

1. In Control Panels, select "Add or Remove Programs."
2. Select MUSICMATCH Jukebox in the list of currently installed programs, and click Change/Remove.

3. Click Yes to confirm you wish to completely remove MUSICMATCH Jukebox.

4. The program uninstalls MUSICMATCH Jukebox.
5. Click OK.

Apple IIGS: Does Not Output Serial Data to Printer Problem/Cure

Problem: Printer does not print when properly configured with an Apple IIGS and connected to the built-in serial port.

This article has been archived and is no longer updated by Apple.

Before you start:

- Familiarize yourself with Apple IIGS technical procedures

- Perform diagnostics per technical procedures

Perform the following in the event that diagnostics did not yield a serial port failure:

Cure 1: A problem might exist with printer switch settings or Apple IIGS Control Panel settings.

Action: Check DIP switch settings on printer and built-in control settings on the computer (see note 1). Reconfigure switches and/or control settings in the computer. Test the system by printing a file to the printer.

Cure 2: A problem might exist with the serial port circuitry that is not being detected by performing diagnostics.

Action: Remove and replace the logic board with a known-good exchange module. Test by printing a file to the printer.

Note 1: The Apple IIGS Control Panel settings can be reset to their defaults by holding down the Ctrl - Command (Open Apple) keys and then pressing the reset key. When the menu appears, select option #2, which says, "Set system standards and 60Hz". The system then automatically re-boots.

iPod for Windows: How to Update MUSICMATCH Jukebox

This document explains how to upgrade the MUSICMATCH Jukebox software that was designed to work with iPod.
This article has been archived and is no longer updated by Apple.
MUSICMATCH publishes an application called MUSICMATCH Jukebox.

A version of MUSICMATCH Jukebox that works with iPod is included with some models of iPod, such as iPod for Windows, and the iPod (with Dock Connector)
models.

Not all versions of the MUSICMATCH Jukebox software work with iPod.

Only upgrade MUSICMATCH Jukebox using the program. Do not download the latest version from MUSICMATCH's website. It may not work with iPod.

Follow these steps to check for an update to the MUSICMATCH Jukebox software installed from the iPod CD:

1. Connect to the Internet.
2. Open MUSICMATCH Jukebox
3. Choose Options > Update Software.
4. If an update to the version of MUSICMATCH Jukebox that works with iPod is available, you will see instructions on how to download the latest version that is compatible with iPod.

Important: The version of the MUSICMATCH Jukebox software that works with iPod may not always be the same version of the MUSICMATCH Jukebox that you can download from MUSICMATCH's website.

Make sure iPod is using the latest version of the iPod Software that is compatible with your iPod model. See these technical documents:

60944, "**iPod: How to Update**"
61907 "**Identifying different iPod models**"

Installing MUSICMATCH Jukebox Software

The MUSICMATCH Jukebox installer automatically opens after Apple's iPod Software installer is finished. Follow these steps to install and set up MUSICMATCH Jukebox.
This article has been archived and is no longer updated by Apple.

Installing Software

1. After the iPod for Windows installer is finished, the MUSICMATCH Jukebox installer open about 30 seconds later.

2. When the Welcome window appears, read the text, and click Next:

3. When the Software License Agreement window appears, read the text, and click Yes if you agree:

4. Fill out the User Registration information and click Next:

You must complete the Year of Birth and E-mail fields to continue. If you click Next and have not filled out these fields, a window appears prompting you to go back and fill out the information:

5. When the Personal Music Recommendations window appears, read the text and select the "Yes (recommended)" or "No" option, and click Next:

If you click Next without selecting "Yes (recommended)" or "No", a dialog appears requesting you to make a selection:

6. When the Installation Options window appears, select the type of installation you want, then click Next:

If you select Express (Recommended), the Copying MUSICMATCH Jukebox Files progress bar appears:

For about a minute, a few more progress windows appear while MUSICMATCH Jukebox continues its installation.

7. If you select Custom, the following dialog boxes appear (otherwise skip to Step 9):
    - You can specify where the software is installed by clicking the Browse button:

Unlike the iPod for Windows software, the MUSICMATCH Jukebox software works properly if installed on a hard disk volume other than C.

    - The Music folder destination can be specified:

- The radio cache can be turned on or off:

- The program icons location can be selected:

- Shortcut locations can be selected:

- File type associations (to MUSICMATCH Jukebox) can be selected:

8. After clicking Next, MUSICMATCH Jukebox begins the installation:

For about a minute, a few more progress windows appear while MUSICMATCH Jukebox continues its installation.

9. Next, the Welcome to MUSICMATCH iPod Plug-in window appears. Click Next:

10. Click Yes to the license agreement if you agree:

11. The MUSICMATCH Jukebox upgrade key is located on the cover sleeve of the installation CD. Enter the key when prompted, then click OK:

Entering the upgrade key allows you to install the MUSICMATCH Jukebox Plus version of MUSICMATCH Jukebox. The Plus version has many extra features not available in the MUSICMATCH Jukebox Basic version (such as CD burning, label making, and so forth.). For a complete list of MUSICMATCH Jukebox Plus features, see to the MUSICMATCH homepage. Both the Basic version and the Plus version have the same iPod support feature set.

12. If the key was entered correctly, the following dialog box appears:

If you selected Cancel or do not type in the correct upgrade key, the Basic version of MUSICMATCH Jukebox is installed. Either version of the MUSICMATCH Jukebox software allows you to manage iPod. The additional features in the Plus version have no direct impact on managing iPod with MUSICMATCH Jukebox.
If the CD sleeve is not available during installation, the upgrade key can be entered later from the MUSICMATCH Jukebox application.

13. As the installation finishes, an alert appears:

14. When the InstallShield Wizard Complete window appears, select one of the two options, then click Finish. Restart the computer after installation:

15. After restarting, you can open MUSICMATCH Jukebox. When it is first opened, these two windows appear:

At this point, you can use MUSICMATCH Jukebox to manage music files. If you are unfamiliar with MUSICMATCH Jukebox's features, use the Help menu in the MUSICMATCH Jukebox window, or go to the Learning More section of the MUSICMATCH website.

iPod 2.0.1: Poor Sound Quality From the Dock‘s Line Out Port

If the USB 2.0 cable is connected to the dock, any compressed music files (such as .mp3, or .wav) may have poor sound quality if you listen to them using the dock's line out port.
This article has been archived and is no longer updated by Apple.

Symptom

The sound quality from the dock's line out port is poor.

This happens when the dock is connected to your computer using the Dock Connector to USB 2.0 + FireWire cable, and the equalizer (EQ) is turned on.

Solution

Use one of these solutions:

- Turn off the equalizer.
- Take iPod out of the dock.
- Disconnect the Dock Connector to USB 2.0 + FireWire cable from the computer. It's OK to keep the FireWire part of the cable plugged into the AC power adapter.

800K Eject INIT: Not Needed with 400K Drives

Does the Apple 800K Eject INIT "park" 400K drives?

This article has been archived and is no longer updated by Apple.
The 800K Eject INIT does not need to "park" the head of a 400K drive. The problem this patch is intended to fix occurs only with the upper head assembly when the disk shutter catches on the upper head as the disk lifts and ejects. Because the 400K drive has only a lower head assembly, there is no danger, and it isn't necessary to park its head. This also holds true for the patch included in System Software 6.0.4 and later Systems. The heads of 400K drives are not parked.

HyperSpeller XCMD Available for HyperCard

Do you know of any spell checkers that work with HyperCard?

This article has been archived and is no longer updated by Apple.
HyperSpeller by Foundation Publishing is a utility that adds spell-checking and search/replace capabilities to HyperCard. HyperSpeller is implemented as two external commands (XCMDs): SpellCheck and FindChange. An installer application places the externals in the Home stack. After installation, SpellCheck and FindChange commands can be issued from HyperCard's message box or a HyperTalk script. The HyperSpeller dictionary file is approximately 164K. It must reside in the System Folder or the same folder as HyperCard.

The user can specify the checking range. For example, "SpellCheck" for the entire stack, "SpellCheck 30" for card 30 on, and "SpellCheck 12,12" for card 12 only. The dialog box clearly states where the suspect word is found. The user can then ask for suggestions, click on the Learn button, or Skip the word to ignore it. A small text box in the dialog shows a limited amount of the context in which the suspect word is found. For users with small monitors, the spelling dialog box can be "zoomed" smaller or larger, allowing the HyperCard card to be more visible.

The FindChange feature gives search and replace capabilities to HyperCard. The Find/Change dialog allows the user to specify "whole word", "match case", "change all", and "Change, then Find". As with the SpellCheck dialog, there is a zoom box that makes the dialog smaller or larger.

For more details, search the Technical Info library under "Foundation Publishing".

Data Access Language (DAL): Server Compatibility

Are versions 1.1 and 1.2 of the CL/1 Server for VMS compatible with AppleTalk for VMS 3.0?
This article has been archived and is no longer updated by Apple.
The existing versions of the CL/1 Server for VMS are 1.0 and 1.1, which are compatible only with AT VMS 2.0, 2.0.5, 2.0.6, and 2.1; not 3.0.

The Data Access Language Server for VMS version 1.2 is shipping as part of DEC PATHWORKS (formerly LanWORKS) for Macintosh, which includes AppleTalk for VMS 3.0. If purchased separately, DAL 1.2 is supported under ATVMS 3.0 OR any one of 2.0, 2.0.5, and 2.0.6 (but not 2.1).

Note: The DAL Client requires a DAL Server. It will not connect successfully to an existing CL/1 Server, and a CL/1 Client will not work with a DAL Server. DAL Server/Client 1.2 will replace existing CL/1 Server/Client 1.1. The released version of PATHWORKS for Macintosh includes DAL Server/Client 1.2.

PATHWORKS for Macintosh (including AppleTalk for VMS 3.0) has been shipping since early autumn 1990 as has DAL Server/Client 1.2.

TA44777_MacintoshtoTandem_Connectivity_Distributed_Sessions_(TIL06199).pdf

Macintosh-to-Tandem Connectivity: Distributed Sessions

I need a gateway product to give networked Macintosh computers access to Tandem computers. Essentially, I am looking for a NetWay 2000-type product for Tandem computers.
This article has been archived and is no longer updated by Apple.
For terminal emulation, TCP/IP and Telnet are available from Tandem.
MacMenlo, from Menlo Business Systems, won't work over TCP/IP, but you can do TTY with TCP/Connect, from Intercon, or even with NCSA's Telnet.

For message passing, we suggest, in addition to TCP/IP, a MacX25 Server. This works relatively well.

Macintosh-to-Sun/UNIX File Transfer

We have a high-end Crossfield Studio color scanner/separation system that I am expanding to provide for a Macintosh front-end. We recommended a Macintosh IIfx with an Ethernet NuBus card and K-AShare file server software to communicate with a Sun SPARCstation (K-AShare is AFP-compatible file server software for UNIX hosts and is sold by Mt. Xinu.)

The reason for the Sun is that the RIP software (StudioLink 2.0) runs only in a UNIX environment. The purpose of the RIP software is to translate the PostScript files from the Macintosh into a native bitmap file that the Crossfield Studio system can understand.

The proposed functionality of the Macintosh-to-Sun link is to provide file transfer to and from the Sun. Once a file is transferred to the Sun, it's archived on a hard disk for eventual processing by the Crossfield system. The Crossfield system is configured around a PDP mini-computer running RSX 11M Version 4.2 operating system. For tying the Sun and PDP systems together, both Digital and Crossfield recommended using DECnet over Ethernet.

Should we have DECnet connecting the Macintosh to the Sun? Is the use of K-AShare an appropriate choice, or is there a better way to connect a Macintosh to a UNIX machine for file transfer capability?

This article has been archived and is no longer updated by Apple.
You should be able to do file transfer between the Macintosh and the Sun using either TCP/IP, DECnet, or the K-Ashare product.

The native networking protocol on the Sun platform is TCP/IP, so you can run MacTCP to communicate between the Macintosh and the Sun.

There are products like TSSnet that allow DECnet on the Macintosh. Sun does provide DECnet on their machines, but we believe you have to pay extra for it.

There should be no compatibility problems for the Sun running all these protocols, because they can share the same Ethernet.

More importantly, there are two things you should take into consideration:

1) Select the product that provides the easiest way for the Macintosh users to transfer files to the Sun. With an AFP-compatible file server, the Macintosh users can just drag the file to the server icon. Using TCP/IP or DECnet, they would need to learn FTP or DECnet COPY, which are not too complicated, but less Macintosh-like.

2) Once the file is transferred to the Sun, can the StudioLink/Crossfield system process the file without any problems? Remember a Macintosh file has a resource fork and a data fork. A minicomputer-based AFP-compatible server stores these as two separate files. Some tests should be done to ensure that the data fork portion file can be processed by the StudioLink/Crossfield system. Also, test to ensure that, if the file needs to be accessed by the Macintosh users afterwards, this can be done.

Published Date: Feb 18, 2012

Data Access Language (DAL): Developer Issues

We have some questions about the use of Data Access Language (DAL).

1) DAL can be ordered from APDA. Does this mean that there will be considerable development work needed when using DAL in the scheme of database access?

2) Using ClearAccess, how much programming and level of knowledge is needed to access Rdb on the VAX system? What utilities or "hooks" are available from DAL that will let me access Rdb via ClearAccess? Do I need to know DAL well before I can use ClearAccess to access the Rdb database?

3) Can our resellers just sell DAL like they do with other applications (like EtherTalk NB Cards, or TokenTalk NB Cards, and so on)? From what I understand, it seems that DAL is a useful tool only if the person using DAL really understands database systems and using DAL utilities to extract and update the information.

4) This pertains to using DAL. If I have a 4th Dimension flat file, and I want to send it to the Rdb database to have it stored as an Rdb record, what must I do and what is the prerequisite (knowledge or software/hardware requirements) before I can do this transfer? Do I, for example, need to convert this 4th Dimension file into an Rdb-readable format for it to update the Rdb record?
This article has been archived and is no longer updated by Apple.
1) Yes, Data Access Language is a development language, and development work is involved to link desktop applications to data processing systems on mainframes and minis. However, for commercial and custom developers, Data Access Language lowers barriers to entry for them. Thus, products and custom solutions can be developed faster/easier because less detailed technical knowledge is required.

Data Access Language is often described as a standard connectivity language that links desktop applications to host data. It is more than just a language; it is really a group of carefully inter-related elements. The elements are the Language, the API, and the Development Aids. Often, the user wants access to different systems without having to worry about protocols, systems, or anything else. Relational databases are becoming more popular because of their ease of use, ease of administration, and application independence. SQL language emerges as a convention for data access language adopted by relational database vendors. SQL, however, is still not a standard. DAL lets software developers create desktop applications with seamless connectivity to DP data and applications without leaving the desktop world. It handles physical network specifics, insulates the desktop application from the operating system, RDBMS, and SQL specifics.

2) The ClearAccess DAL interface provides a series of dialog boxes that let users build queries by pointing and clicking. Users do not need familiarity with all the details of DAL or SQL. End users without knowledge of programming and SQL can access the databases via the dialog boxes, which build the SQL statements for them. The amount of knowledge required really depends on how complex the database access is going to be. A background in relational databases would also help.

3) Again, it really depends on the solutions. For simple ad-hoc queries and databases updates, DAL with a HyperCard or ClearAccess interface will let end users do the job without a lot of training. For complex, customized business applications that need to take advantage of the Macintosh interface, some serious planning and design should be done. Large companies with an in-house MIS programming staff should be able to do this task.

4) You can tell 4th Dimension to export this file with certain delimiters, transfer the file to the VAX, and import it into Rdb. This can be done without using DAL. You must be familiar with the export capabilities of 4th Dimension, know how to transfer the file to the VAX, and know how to import it into VAX/Rdb.

If this is going to be done by end users on a routine basis, please note that DAL provides 4th Dimension External procedures that let 4th Dimension applications act like CL/1 clients and create distributed applications on the Macintosh. You must know how to program 4th Dimension External procedures to export the data to the DAL server on the VAX host. You should also know how to install the DAL software on both the VAX and the Macintosh and the standard network connection between the Macintosh and VAX host.

AppleTalk Phase 2: SNAP Encapsulation with OUI=0

My problem is that the AppleTalk Phase 2 ARP uses a SNAP encapsulation with an OUI=0 ("Organizational Unique Identifier"). Because Translating FDDI/Ethernet bridges use this OUI to pass Ethernet 2 packets to FDDI and back, an AppleTalk ARP gets converted to an Ethernet 2 packet when passed from FDDI to Ethernet. This packet format is not accepted by Apple host implementations. Therefore, it's not possible to use AppleTalk Phase 2 with FDDI with translating bridges between two AppleTalk hosts.

We need a solution.

This article has been archived and is no longer updated by Apple.
The all-zeros "Organizational Unique Identifier" (OUI) was not specifically intended to be used for translating Ethernet frames to 802.2/SNAP. Its original intent was (and is) not completely clear; all that was generally agreed upon was:

1) The low-order 16 bits of the SNAP protocol discriminator indicated an Ethernet protocol type.

2) The format of the data part of the SNAP packet was the same as the format of the data part of the Ethernet packet of this protocol type.

This "general agreement," as far as we know, was never written down. AppleTalk Phase 2 and TCP/IP both adopted this convention. The unfortunate difference is that, on an Ethernet/802.3 data link, AppleTalk Phase 2 runs on top of 802.3 (and 802.2) and TCP/IP runs on top of Ethernet. Thus, for a TCP/IP Ethernet node to communicate with a TCP/IP 802.2 node (on Token Ring or FDDI, for example), some type of packet translation must be done. On the other hand,for an AppleTalk Phase 2 Ethernet node to communicate with any other AppleTalk Phase 2 802.2 node (on Ethernet, Token Ring, or FDDI), no such translation is necessary (in fact, such translation MUST NOT occur).

This makes it somewhat difficult to build a bridge that "transparently" allows both forms of communication. However, all that really has to be done is for the bridge to contain a small table of Ethernet protocol types that either should, or shouldn't, be translated in this manner. Obviously, the smaller the table, and the less translation done, the better the overall performance. Any bridge between Ethernet and an 802 media that does not translate any OUI zero packets will prevent TCP/IP nodes (and any others using the same OUI convention) from communicating between the two media. Any bridge between Ethernet and an 802 media that translates all OUI zero packets will prevent AppleTalk nodes (and any others with an OUI of zero that don't expect translation) from communicating between the two media. In both cases, routers can, of course, be set up to accomplish the communication.

A somewhat equivalent problem could exist if two bridges are used to connect two Ethernet/802.3 data links across an 802 backbone (say, FDDI). In this case,some type of translation/encapsulation of Ethernet (non-802.3) packets must be performed to allow them to be passed across the 802 backbone. There are many ways to do this, one of which seems to be translating all Ethernet packets to OUI zero packets, shipping them across the backbone, and then converting them back. This, however, does not work for any OUI zero packets that start out on the Ethernet/802.3 data link. Such packets will not be translated on the way into the backbone, but will be incorrectly translated before being delivered on the destination Ethernet. Such packets should be forwarded entirely without translation.

In terms of actual product implementations, unfortunately, DEC is already testing an Ethernet-to-FDDI bridge that translates all OUI zero packets and, thus, does not work with AppleTalk Phase 2. They are aware of this issue. At

the recent 802 meetings in Denver, it became clear that this type of translation is not part of the 802.1d (Macintosh Bridging) standard, but is something that many bridge manufacturers want to include as a non-802-standard option with their products. Most have said that they will have some type of translation (or non-translation) table to ensure that it works with all known protocols.

Serial Line Interface Protocol (SLIP) and MacTCP

I heard that Apple supports SLIP (Serial Line Interface Protocol) added on to MacTCP. Could you explain SLIP? Will MacTCP (future versions) support SLIP?

This article has been archived and is no longer updated by Apple.
SLIP is an asynchronous, serial line protocol developed for running TCP/IP over serial communications lines in a point-to-point configuration. SLIP was developed to transmit IP packets over low-speed, sometimes noisy, asynchronous communications lines where error recovery and an efficient line protocol are needed. The SLIP protocol is now being replaced with a new serial line protocol named "PPP", which uses a more efficient means of establishing a point-to-point IP connection.

MacTCP 1.0.2 includes hooks that let third-party developers write different link-layer modules. This makes possible the development of interfaces to SLIP, PPP, and to any other link layer that someone may need, like broadband, X.25, FDDI, and so on. Apple does not provide support in MacTCP for SLIP or any other serial line protocol; these have to come from third-party developers.

A/UX 2.0: Display Card 8/24 in a Macintosh IIfx

I thought that the Display Card 8/24 supported the Two-Page Monochrome Monitor under A/UX 2.0, provided you use 1-bit mode. But I have an installation where this did not work. The system was a Macintosh IIfx (upgraded from a Macintosh II). A/UX was supplied as an official released seed version of 2.0. Knowing that there were some early beta cards that would not work, I checked the card. It was clearly labeled "trident" and was ordered through regular channels (no indication of being beta).

After a clean installation, the machine would freeze with a blank screen during the startup process. It appeared to go through A/UX loading, but froze when it was building the Macintosh side. After swapping the card and monitor with a regular color monitor and card, things started up fine.

Can you explain?

This article has been archived and is no longer updated by Apple.

It is not always true that the Display Card 8/24 and a Two-Page Monochrome Monitor work under A/UX 2.0 on a Macintosh IIfx set to 1-bit mode. We tested a Macintosh IIfx, running A/UX 2.0, with a Display Card 8/24 and a Two-Page Monochrome Monitor:

We did a cold start (power-off, then power-on) in 1-bit mode. A/UX 2.0 didn't start up and froze during the startup process. However, if the interrupt button (on the right side of Macintosh IIfx) was pressed, A/UX continued the startup with no problems.

If the Autolaunch command within the #startup shell was modified to have only the "launch" command (without the -s option, load symbol table in the kernel), A/UX 2.0 started up successfully in 1-bit mode.

The Display Card 8/24 and Two-Page Monochrome Monitor seem to start up A/UX 2.0 fine on other Macintosh II machines, including the Macintosh IIx.

A/UX: Using "dd" To Copy Partitions (9/94)

One way of copying A/UX disks is to do a "dd" copy of the various partitions. This is particularly useful on large disks, or when a CD-ROM is not available. However, if you do a "dd" copy, the file system is also copied. This may cause problems on drives that do not like the way Apple has fine-tuned the file system for its files (some drives come with their own parameter files for creating file systems--so that the Generic file is not used).

1) Is this true?

2) Does it make a difference if you specify "rdsk" or "dsk"?

3) Are there better ways to install A/UX on large disks (in particular, allowing larger root&usr partitions), like special versions of tar?

This article has been archived and is no longer updated by Apple.
1) Yes, "dd" is often used to do an entire image copy from one hard drive to another of the same size. For instance, to copy an Apple HD80 SC to another Apple HD80 SC, use this command:

dd if=/dev/dsk/c0d0s31 of=/dev/dsk/c5d0s31 bs=20k

It also can copy file system by file system (with the same size). For example, to copy one A/UX root file system to another, do:

dd if=/dev/dsk/c0d0s0 of=/dev/dsk/c5d0s0

Since it is an imaging copy from one hard drive to another, everything, including partition map and super block information in the file system, is copied to the destination disk or partition. Therefore, size differences are significant. If you "dd" an entire HD80 SC to an HD160 SC, only 80MB is usable on the HD160 SC.

The two hard drives do not necessarily have to be the same brand. For instance, you can copy from an Apple HD80 SC to a third-party 80MB hard drive, or copy the root file system from an A/UX CD-ROM drive to an Apple HD80 SC A/UX root file system.

2) There is no particular difference when specifying "dsk" or "rsk"; they give the same result. However, specifying "rdsk" (raw device I/O) seems to be much faster than "dsk" (block device I/O) because, under raw I/O, there is no block transfer size constraint by the file system logical block size--it can transfer many disk blocks per disk operations.

3) If the non-standard procedures section in the "A/UX Installation Guide" documentation does not meet your needs, you can install A/UX on large disks with larger Root&Usr partition than the standard size. For instance:

- Initialize and partition the large disk with the desired Root&Usr size. This can be done using the vendor formatter software or the A/UX "dp" utility.

- Make a new root file system. For example:

newfs -s size device-file type

- Mount the new root file system on a directory. For example:

mount /dev/dsk/c5d0s0 /big

- Use "cpio" to copy the standard A/UX Root&Usr file system to a new one. For example:

```
find / -depth -print | cpio -pdlmu /big
```

DAL: Needs MacDFT 1.1 & MacMainFrame Network Adapter

I installed DAL (formerly CL/1) for VM/CMS onto an IBM 370. The installation on the host seems okay. I was able to execute the icl1 module on the host. When I tried to connect to the host using a Macintosh, the connection failed. When I tested the connection using cl1 Tester, which comes with the DAL Developer's Toolkit, I got Error -10646. What could have caused this problem?

Here is a list of the hardware and software I used:

- Apple Coax/Twinax cable with MacDFT version 1.0.
- DAL Server for VM/CMS version 1.1
- DAL Developer's Toolkit version 1.1

This is the configuration I used for the host.cl1:

vma:3270mac:VMCMS:CUT:A
vma:login:1:\\mRUNNING\\slogoff\\r\\mcontinue\\r\\mVIRTUAL\\svmexit\\r:1800:6000:\\^x:\\M
logon\\svm\\r\\mVIRTUAL\\r\\muserid\\slogon\\u\\r\\mpassword\\p\\r\\w20\\n\\w20\\mReady\\n

Also, I would like to test the connection with the Avatar MacMainFrame card. I was told that I need the network adapter from DCA (formerly Avatar). What is this network adapter?
This article has been archived and is no longer updated by Apple.
Error -10646 translates to "Cannot Load Network Adapter", the driver associated with the communications board in use. From your description of the problem, the most likely reason for this is that MacDFT 1.1 is required. Update the software, and everything should work as advertised.

The network adapter is DAL driver software, specific to MacMainFrame. It is available from DCA (formerly Avatar).

As of DAL release 1.2 all DAL releases ship with all the available network adapters. You non longer need to contact the network communications companies for the individual DAL pieces.

APT Routers Support Device Security Across Zones

How can I get device security across AppleTalk zones?

This article has been archived and is no longer updated by Apple.
APT has announced an update to their AppleTalk routers. They now support device security across zones. Users can hide a LaserWriter, file server, or shared modem from anyone not in their zone.

Users in different zones can be allowed different sets of access to different devices. For example, Zone A may have no access to your LaserWriter but still have access to a file server, while Zone B has access to all LaserWriters but not AppleTalk ImageWriters or NetModems.

APT routers connect multiple LocalTalk, Ethernet, WAN, and Serial networks, and they support AppleTalk Phase 2.

A/UX : Backup and Restore Functions

Is special software required to back up A/UX drives? If files are restored, does UNIX need to be notified in any way?

This article has been archived and is no longer updated by Apple.

All versions of A/UX come with software utilities, such as "dump.bsd" and "restore", to back up and/or restore A/UX file systems from a disk drive to a tape backup device. Third-party tape drives can be used if they support the tape driver.

You run the "rdump" and "rrestore" utilities to back up and restore a remote UNIX file system to and from the tape drive. Other utilities, like "cpio", "tar", and "dd", can also be used to back up or restore individual file(s) in different formats.

To create a backup:

```
tar cvbf 16 /dev/rmt/tc<#> <filename>
```

where <#> is the SCSI id number of the tape device and <filename> is the name of the directory or file to backup. Or use:

```
dump.bsd 0ubf 16 /dev/rmt/tc<#> /dev/dsk/c0d0s0
```

where <#> is the SCSI id number of the tape device and an entire filesystem is specified.

Note that the tar command uses a filename specification while the dump.bsd command uses a device name specification.

To check what is on a tar backup, you can get a "table of contents" with

```
    tar tvf /dev/floppy0
or
    tar tvf /dev/rmt/tc#
```

where # is the SCSI id of the tape device.

To extract files from a tar backup:

```
    cd <dir where you want files to go>
    tar xvf /dev/rmt/tc#
```

When files are restored, they are automatically restored to the original format, depending on the command option(s) used.

For more information on the backup and restore functions, please refer to manual pages rdump(1M), dump.BSD(1M), restore(1M), rrestore(1M), tar(1), cpio(1), and dd(1).

A/UX: Optimizing for Current Memory (8/93)

I have an 8MB Macintosh IIfx running A/UX that I want to optimize for performance at that memory configuration. I have read the Tech Info Library article "A/UX: How to Improve File Access Speed", and I have some questions.

If you run a "newconfig" command while under A/UX, will it automatically build a new kernel that is optimized for the current memory in the system? Will "autoconfiguration" at startup time notice that I have more physical memory than the kernel is optimized for and carry out this kconfig command for me?

This article has been archived and is no longer updated by Apple.
Prior to A/UX 3.0 when a "newconfig" command is used to build a new kernel, the file "/newunix" is used as the base for the new kernel. Therefore, the new kernel (/unix) parameter values, like NBUF, NINODE, NFILE, and so on, will be reset to the default from /newunix. To keep the current kernel parameter values when the new kernel is built, use this:

```
# cp /newunix /newunix.orig #! Save the original newunix
# kconfig -n /unix #! Modify kernel parameters
# cp /unix /newunix #! Copy the current kernel to newunix
# newconfig #! reconfig the new kernel
```

The new kernel will be built with the current kernel parameters.

If you want to build a new kernel based on the original, the /newunix.orig can be copied back any time. For example, cp /newunix.orig /newunix.

With A/UX 3.0 and higher, the above process is not necessary because the parameter values, like NBUF, NINODE, NFILE, and so on, are kept and become part of the new kernel.

If there is new hardware (like an EtherTalk NB Card) to be added to the system, A/UX will automatically configure it when A/UX is started up. The file "/newunix" is also used as the base for the new kernel.

Here is a description of booting/launching decision:

When A/UX Startup is launched, by default, it performs:

* AutoRecovery, which checks the root file system with the command:

/dev/default

If the file system check is successful, do:

* AutoLaunch with the command: launch

The launch command first checks the default kernel against the hardware. Because no kernel is specified on the command line, the contents of file /nextunix, which is /unix, is used by launch. If the kernel matches the hardware, the /unix kernel is used to start up A/UX. If the kernel doesn't match the hardware, the launch command uses the /newunix kernel instead to build the new kernel, and the new kernel is placed on /unix.

MacX: MacTCP Configuration Problem

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

I'm having a problem setting up MacTCP (to use MacX). I'm trying to run MacX from the Macintosh OS (as opposed to A/UX). I have an Ethernet connection between my Macintosh IIx and a RISC UNIX box running X/MOTIF over TCP/IP. The entire Ethernet consists of the UNIX box, two TCP/IP X-stations, and three Macintoshes. There are no routers, gateways, Domain name servers, RARP, or BootP servers on the Ethernet. The Macintoshes can talk to each other via EtherTalk just fine. Also, I can see the UNIX box and X-stations communicate by running EtherPeek on one of the Macintoshes.

I installed the Communications Toolbox, moved the MacTCP Tool (that came with MacX) into the "System Folder:Communications Folder", and moved the MacTCP CDEV files into the System Folder. I also followed the advice in the "MacTCP Setup Tips".

I configured MacTCP (the CDEV) by bringing it up in the Control Panel. I selected:

- Ethernet (as opposed to LocalTalk)
- Address "Manual" (and entered 192.0.0.4)
- No Routing
- No Domain Name information

I restarted. (The AppleTalk connection is set to LocalTalk.)

When launched, MacX displays an alert with the message: "None of the connection tools are working at the moment--check that they are properly installed and restart MacX. Until this is done, no incoming X-client connections can be accepted."

I tried this with both the MacTCP files that came with MacX and those I got separately from APDA, and had the same results.

Specific Questions
---
1) How do I tell MacX what the address of the UNIX box is, or if MacX is really a network "server" on Ethernet, how do I tell it what its name is?

2) Is the MacTCP host file needed?

3) Does the Communications Toolbox tool MacTCP expect anything special of the MacTCP CDEV?

Additional Information

I have a copy of NCSA Telnet (for MacTCP) that will not run on the Macintosh IIx described above. Unfortunately, it doesn't display an error message; it just displays its initial banner and quits after about 5 seconds.

Can you help?

TA44793_MacX_MacTCP_Configuration_Problem_(TIL06218).pdf

This article has been archived and is no longer updated by Apple.
According to the information that you provided, the MacX and MacTCP installation procedure seems to be correct. One thing that should be made more clear is the "MacTCP Tool" must be put in the "System Folder:Communications Folder" folder.

We found that there is a problem using the IP address 192.0.0.4 in the MacTCP configuration, which we think is not a valid class C network number. In a class C network, 192.0.0 is a reserved network number, and it should not be used by any MacTCP configuration. This might be the reason that MacX is displaying the warning message. IP address 192.0.1.4, for instance, can be used as a valid IP number.

Make sure that the network number specified in the MacTCP IP address is valid and is the same network number as the other UNIX machine on the Ethernet.

If MacX and the UNIX box are configured correctly and connected on the network, their IP addresses should be known to each other. Also, on a UNIX box, you can issue the "ping" utility to send an ICMP packet to a MacX server to see if it is up or not. On the MacX server side, you can run the "MacTCP Spy" to see if the MacTCP is up running.

MacX is just a network "display" server, not a network server, in general, like an NFS. If your MacTCP is configured with a Domain name server, all name inquiries can be via the Domain name server. The host file is not necessarily needed. The "MacTCP Tool" does not need a "special" version of the MacTCP CDEV.

A/UX: File System Limits

Article Change History

10/17/90 - REVIEWED
* For technical accuracy.

What is the limit of the A/UX file system?

This article has been archived and is no longer updated by Apple.
The total size of an A/UX file system (both UFS and SVFS) is measured in blocks. The number of blocks is stored in each file system's super block with the declaration of "long fs_size". This value can be stored up to 2**32 blocks. The block size of the file system in UFS, for instance, can be 512 bytes, 1K, 2K, 4K, or 8K. In SVFS, the default file system block size is 1K.

From the number of blocks and the file system block size, the maximum size of an A/UX file system ranges from 2**32 Kbytes to 8*2**32 KB.

Printers: Difficulties With 9-Part Forms

Can you recommend a third-party printer product that prints a 9-part tractor feed form?

This article has been archived and is no longer updated by Apple.

We were unable to find a printer on the market that prints a 9-part form. The closest we found was one manufactured by Toshiba that prints up to 6-part forms.

The problems encountered with 9-part forms concern the print head. To put enough power behind the pins of a dot matrix to print on the ninth part of the form, the pins will penetrate the first and probably the second part of the form, leaving holes. Also, the pins often get caught in the form as it moves and are bent and the print head needs to be replaced. Unfortunately, printers designed for microcomputer use just aren't up to the task of printing 9-part forms.

Daisy-wheel printers have similar problems. The energy demanded to print through nine layers would break a plastic print wheel and bend metal print wheels out of shape.

Even heavy-duty Printronix line printers are rated only to 6-part forms.

We suggest that you contact the paper company that makes the 9-part forms and ask what printers they recommend for use with these forms.

AlisaTerminal: Now Supports More Zones

We have had a problem with a WAN. The backbone is connected via cisco routers. They are still mostly at Phase 1. The network worked flawlessly, except for AlisaTerminal. It would look for the DECnet gateway and then hang. After numerous attempts to resolve the problem with Alisa, Alisa agreed that AlisaTerminal had "problems" negotiating with more than 39 zones. (We had a little over 100.)

This article has been archived and is no longer updated by Apple.

Alisa now has an updated AlisaTerminal, available from their Technical Support.

We tested the new AlisaTerminal, and it appears to work with 100 zones. The new AlisaTerminal has an added function--you can force additional queries of the network by pressing the Command key and clicking on the Host dialog box.

A/UX 2.0: Restricted Login Problem

I want to set up a restricted account through the chroot command. The man pages for login say that you should be able to do this by using a "*/etc/passwd" in the place of a shell to be executed at startup. I tried to duplicate the problem and documented it below. If this is a bug that is not fixable in the near future, can you suggest a way to set up a restricted account, so that it has no way of getting to /? How is this done on the patch server?

Man page excerpt from login:

If the last field is *, then a chroot(2) is done to the directory named in the directory field of the entry. At that point, login is re-executed at the new level, which must have its own root structure, including /etc/login and /etc/passwd.

User toad's login sequence, it looks like it is trying to execute "*".

Apple Computer A/UX (ebc_A/UX)

login: toad

This article has been archived and is no longer updated by Apple.

This is a bug in the A/UX 2.0 login(1) command. You would not be able to reproduce this by logging in to the

console under A/UX 2.0. This feature is a part of the System V login(1) command, which is not executed when logging in to the A/UX console. Instead the /mac/bin/Login program is called, and it does not understand the "*" syntax in the /etc/passwd file. Even when logging into the serial ports or the console when /mac/bin/Login is not present, the chroot does not work. This is one reason why the patch server is still running A/UX 1.1.1.

You should use rsh(1) as a replacement for the functionality that has been lost in the A/UX 2.0 login command until a fix is provided. rsh would normally be the way to accomplish restricted login anyway.

Published Date: Feb 18, 2012

MacTCP: Gateway Address; TokenTalk Support

Here are two MacTCP 1) What is the "gateway address" box? I know that this is not the address box for a DDP/IP gateway (like a FastPath) for providing server-based addressing. The MacTCP Admin manual mentions that this "gateway address" has something to do with network access when full RIP support is not available.

2) I've seen that MacTCP works with "TokenTalk" (not native TCP support for Token Ring). Is this an "officially supported" configuration?

This article has been archived and is no longer updated by Apple.

1) The MacTCP Control Panel setting for the "gateway address" does not have any function in relation to the DDP/IP gateway used for TCP/IP encapsulation in AppleTalk. The "gateway address" is used when MacTCP is talking native TCP/IP over Ethernet. If your network does not have a RIP (Route Information Protocol) process running on a router connected to the network, the default gateway address is used to locate routes to "smart" gateways, which might be connected to much larger outside networks, like the Internet. Most BSD UNIX systems are capable of running a RIP process.

2) Yes, we support running TCP/IP encapsulated in AppleTalk over Ethernet, Token Ring, or LocalTalk. The physical media does not play a large part in the ability of an encapsulating protocol to function properly.

Published Date: Feb 18, 2012

TokenTalk Support For Novell Token Ring

I understand that there is still no driver available that lets Netware for the Macintosh support Apple's TokenTalk NB Card in Novell's Token Ring environment. Is there a workaround to this problem?

I am running Novell Netware (version 2.15, revision C) on a Token Ring with a PS/2 as server. They have both the compact and modular Macintoshes.

An article mentioned a workaround using an Macintosh IIcx, running as a router between the Macintoshes on TokenTalk and the PS/2 server.

"The router will consist of a TokenTalk NB Card and an EtherTalk Card running to the PS/2 Model 80 running whatever Ethernet card they choose that will work with EtherTalk (that is, 3COM, and so on)."

What I'm not clear about is whether the PS/2 server running Netware automatically supports routing between Ethernet packets and Token Ring packets (on the Novell Token Ring side). Is there additional software required on the PS/2 server?

Will this configuration support transparent file and print services for the Macintoshes as well as electronic mail between the Macintoshes and Novell Token Ring machines?

This article has been archived and is no longer updated by Apple.
Novell has stated that TokenTalk support can be ordered. This will be a new version of VAP (Value-Added Process), which supports AFP (Apple Filing Protocol) 2.0 and TokenTalk.

All Netware operating systems provide an internal router that lets a Netware server connect to four different networks. No additional software is required. Note that the routing service can also be moved out of the server and into a non-dedicated workstation.

Macintosh, DOS, and OS/2 workstations can share data and resources. Macintosh users should see information stored on the network server as icons. Other workstations on the network (PCs running DOS, OS/2, or Windows 386) should see the folders and file icons from the Macintosh listed as directories and subdirectories in their workstation formats. DOS, OS/2, and Macintosh users can share Apple LaserWriters and other Apple printers. Using an E-mail package that supports Netware Message Handling Service (MHS), the back-end store-and-forward messaging server, you should be able to send E-mail messages and text, data, binary files between different LANs, and wide area networks.

TokenTalk NB Card: Compatibility of RasterOps Video Card

I have been having compatibility problems with RasterOps video cards and Apple's TokenTalk NB Card.
This article has been archived and is no longer updated by Apple.
RasterOps identified and corrected some problems with their 224/724 cards. The problems occurred on Macintosh computers with a 224/724 card and TokenTalk NB Card.

1. No video on the 224/724 card at powerup.
2. Selecting 24 bits/pixel on the 224/724 card causes pixels to change color under the cursor (and at random on the startup screen).
3. Zones and servers appear and disappear.
4. In all of the above cases, eventually a bus error (ID=1, sometimes ID=28) system bomb occurs.

The fixes are hardware rework. All finished goods and cards shipped since early May 1990 should contain this fix. Customers with problems should contact the RasterOps Technical Support department.

A/UX: LaserWriter "typescript...log" Installation Problem

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I am having problems installing a LaserWriter under A/UX. Why does it seem to think that "typescript...log" is the device?

This article has been archived and is no longer updated by Apple.
There is a link between typescript...log (that whole line of stuff) and the actual LaserWriter device. Reinstall the LaserWriter, without other printers installed. Then type ADD_LW and it'll work fine.

Published Date: Feb 18, 2012

A/UX: Autoconfig Cannot Find Drivers Error

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I got the error: "Warning cannot find driver(s) for device ID XX Version X.X".

This article has been archived and is no longer updated by Apple.
For any slot card that Autoconfig cannot find a module in the kernel with a matching board and version number, Autoconfig prints a warning message to the system console.

For example, if autoconfig cannot find the driver for an Ethernet card you have installed, it prints a message similar to the following:

Warning cannot find driver(s) for device ID 5 Version 7.0

It is just an informational warning and does not signify any real error.

If the card is a monitor card, then the error is irrelevant, since the card will work with the default monitor kernel driver.

TA44828_AUX_About_etcstartup_(TIL06260).pdf

A/UX: About /etc/startup

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

What does the text in /etc/startup mean?

This article has been archived and is no longer updated by Apple.
Each line in the file /etc/startup lists the startup program to be executed at system boot time and the arguments to be passed.

The options are as follows:

"-M" followed by a number specifies the major device number.

"-C" followed by a number specifies the number of controllers associated with this module in the system.

"-D" followed by a number specifies the number of devices per controller.

"-S" specifies the NuBus slot in which the controller exists.

For example, the line:

/etc/startup/TEST -M 9 -C 1 -D 1 -S 11

within the /etc/startup file indicates that the TEST module has a major device number of 9, has one slot associated with it in the system, has one device per slot card, and is installed in slot 11.

A/UX: How to Create an NFS Kernel (9/94)

How do you create an NFS kernel?

This article has been archived and is no longer updated by Apple.
For A/UX 3.0, to make a kernel that supports NFS, open the Command Shell window and enter this command:

newconfig nfs

If this is the first time that the Ethernet driver has been included in a kernel on this computer, newconfig displays the prompts that allow you to define the TCP/IP connection for this machine. Regardless of whether the computer has already been configured to connect to a TCP/IP network, the newconfig command also prompts you for information about NIS.

In addition to making a new kernel, the newconfig command enables nfsd, biod, mount, rpc.statd, and rpc.lockd in the /etc/inittab file. Enabling nfsd is required for the computer to be an NFS client.

When newconfig is done, increase the number of kernel memory buffers by running the kconfig command:

kconfig /unix

NMBUFS=1000

(CONTROL-D)

If the computer has 8 MB or less of physical memory, you should also increase the value of MAXCORE by entering this command while running kconfig:

MAXCORE=0x60000

If the computer has more than 8 MB of physical memory, the memory allocation routines in the kernel dynamically adjust the value of MAXCORE. The new values for MAXCORE and NMBUFS cause the allocation of more of the kernel memory buffers that NFS uses, which improves server performance.

Choose Restart from the Finder's Special menu. When A/UX is up, the computer should be an NFS file server.

To verify, log in and run ps to see that the appropriate number of nfsd processes are running. You can determine that number by checking the nfsd entry in the /etc/inittab file. The default number is 4.

If the nfsd processes are not running, check the nfsd entry in /etc/inittab and restart your computer again. Next, verify that the pathnames specified in /etc/exports can be mounted. To do so, enter this command:

showmount -e

This is an example of the response, assuming that the entry is /etc/exports on hostname1 is

/usr/catman -access=hostname2

The response would be

export list for hostname1:
/usr/catman -access=hostname2

Finally, check /etc/inittab to verify that the entries in your file match the entries shown here:

nfs3:2:wait:/etc/nfsd 4 # set to "wait" for NFS server

nfs4:2:wait:/etc/biod 4 # set to "wait" for NFS client

nfs5:2:wait:/etc/rpc.statd # set to "wait" for NFS status monitor

nfs6:2:once:/etc/rpc.lockd # set to "once" for NFS lock manager

nfs8:2:once:/etc/mount -at nfs > /dev/syscon 2>&1 # set to "once" for NFS

For additional information, refer to the A/UX Network System Administration manual.

A/UX: How to Build a Kernel Without Networking

How do you build a kernel without networking?

This article has been archived and is no longer updated by Apple.
To build a kernel using the Autoconfig command:

1) Log on to the system as "root".

2) Enter the command: /etc/newunix nonet

3) Enter the command: autoconfig

The output of the Autoconfig command might look similar to this:

Warning cannot find driver(s) for device ID 5 Version 7.0 Ignore the message: 'ld warning: file /tmp/kernAAAa02712 has no relocation info' if it appears. ld warning: file /tmp/kernAAAa02712 has no relocation information

Module Board Prefix Major Flags
====== ===== ====== ===== =====
0: scc 0 init-??? present char
1: scsi 24 init-??? present block
2: tty init-??? present
3: streams init-??? present
4: slots slots init-normal included lib
5: toolbox ui_ 4 init-normal included char fork ex

The last few lines of information sorted by columns describe the modules currently included in the kernel. You should not see any lines in the output that contain "nfs", "bnet", or "ae6".

Note: To make use of the new kernel, you must reboot the system.

What is an NFS client? An NFS server?

This article has been archived and is no longer updated by Apple.
An NFS client is a UNIX system that has mounted file systems of another UNIX system. The UNIX system which lets these file systems be mounted over the network by clients is called the NFS server.

A/UX: Configuring the Kernel for an NFS Server

How do I install NFS (configure the kernel) for an NFS server?
This article has been archived and is no longer updated by Apple.

```
If you are using A/UX 2.0 or 3.0, bring the system to single-user mode and type the command:

   newconfig nfs

Then, follow the steps below:

1) Edit /etc/exports to specify hosts eligible to mount file systems from
  this server. In this file, you will specify what partitions you will
  allow to be mounted and what systems may be mounted.

  For example: to let anyone on the system "hostname1" mount a file
  partition named "/u1", you would enter the line to /etc/exports:

      /u1   hostname1

2) Check that a file system has been exported to this system; enter the
  command-line: showmount -e

  The output should look similar to the following:

      /     hostname1
      /users   hostname1 hostname2
```

A/UX: How to Mount a Remote NFS System Manually (9/94)

How do I manually mount a remote NFS file system?

This article has been archived and is no longer updated by Apple.
The following steps use fictional directory and system names to give an example of how to manually mount a remote file system.

1) Log on the system as "root".

2) You will need a directory on which you will mount the remote file partition. Let's call the directory "mntdir".

3) Enter the line: mkdir /mntdir

This creates the directory mntdir in "/".

4) Next, we need the name of the remote file partition. We'll use the /usr/catman directory on the remote system "my_system_name" as an example.

5) Enter the line: mount my_system_name:/usr/catman /mntdir

This command line mounts the /usr/catman from the system "my_system_name" onto the "/mntdir" on the local system.

6) To check that the partition is actually mounted, type the command "mount" and press Return. Among the output, you should find one line for the remote partition just mounted:

my_system_name:/usr/catman on /mntdir

A/UX: How to Mount a Remote NFS System Automatically (9/94)

How do I make a remote NFS file system mount automatically at startup?

This article has been archived and is no longer updated by Apple.
1) Log on the system as "root".

2) First, remember that you will need a directory on which you will mount the remote file partition. Let's call the directory "mntdir".

3) Create the directory mntdir in "/"; enter the command-line:
mkdir /mntdir

4) You need the name of the remote file partition. Use the /usr/catman directory on the remote system "my_system_name" as an example.

5) Edit the file /etc/fstab. This file contains a list of file partitions that will automatically be mounted at boot time.

6) Add the line: my_system_name:/usr/catman /mntdir nfs rw,soft 0 0

7) Save the file and exit the editor.

8) Shut the system down.

9) Bring the system back up into multi-user mode.

10) The names of the local and remote partitions will be listed as they are automatically mounted.

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

What's /etc/nfsd?

This article has been archived and is no longer updated by Apple.
/etc/nfsd is a Network File System (NFS) daemon. The nfsd daemon starts the NFS server daemons that handle client file system requests.

Published Date: Feb 18, 2012

A/UX: Daemons Needed for NFS (9/94)

What daemons need to be running for NFS?

This article has been archived and is no longer updated by Apple.
By using the "ps" command, you can determine if all the NFS daemons necessary for an NFS server are running.

1) Log on to the system as "root".

2) Enter the line: ps -ef

3) If all the necessary daemons are running, you should find these lines within the output:

root 98 1 0 09:42:27? 0:00 /etc/portmap
root 100 100 0 09:42:28? 0:00 /etc/nfsd 4
root 102 100 0 09:42:29? 0:00 /etc/nfsd 4
root 103 100 0 09:42:29? 0:00 /etc/nfsd 4
root 104 100 0 09:42:29? 0:00 /etc/nfsd 4
root 116 1 0 09:42:37? 0:00 /etc/inetd

The above lines may not appear together, and the numbers in the columns may differ on your system.

If you don't have the nfsd 4 lines appear, you may try the following procedure to start the /etc/biod daemon.

1) Log on as "root".

2) Edit the file /etc/inittab

3) Enter these changes:

- Change this line: nfs4:2:off:/etc/biod 4

- To this line: nfs4:2:wait:/etc/biod 4

- Change this line: nfs8:2:off:/etc/mount -at nfs > /dev/syscon 2>&1

- To this line: nfs8:2:once:/etc/mount -at nfs > /dev/syscon 2>&1

4) Now, when your system is booted into multi-user mode, the daemon will automatically be started.

A/UX: How to Use showmount

How do I use showmount?

This article has been archived and is no longer updated by Apple.
The "showmount" command lists remotely mounted or exported file systems. The showmount command executed with no options lists the systems which have file systems remotely mounted from your system. Here is some example output from "showmount":

my_system_name
grumpy

This output tells us that the systems "my_system_name" and "grumpy" have partitions mounted from your system.

The showmount command has three options:

"-d" This option displays a list of the directories being remotely mounted from your system.

"-e" Prints a list of exported file systems.

"-a" Displays a list of hosts/remotely mounted directories sorted by hostname.

By using the "-a" option with the /usr/etc/showmount command, you can get a list of directories remotely-mounted from your system, sorted by the hostnames on which they are mounted.

Example output from the command line "showmount -a":

machen:/
machen:/users
redpony:/usr
redpony:/usr/catman

This example shows that the system "machen" has the "/" and "/users" partition mounted on his system while the system "redpony" has "/usr" and "/usr/catman" remotely mounted.

A/UX 3.0: How to Set tty to Work With cu (8/94)

What tty do I use with cu?

This article has been archived and is no longer updated by Apple.
The Macintosh has two serial ports called tty0 and tty1. The cu command is used to dial out and requires complete control of the serial port you tell it to use. That means that the getty process, which runs on serial ports waiting for users to dial in, must not be active on a serial port that is being used for dial-out purposes.

To set up the serial port so that it can be used for either dial-in or dial-out purposes, modify the /etc/inittab file so that the value of the action field of the serial port is respawn. Here is an entry for tty0:

00:2:respawn:/etc/getty tty0 mo_2400 # Port 0 (modem)

When you are finished editing /etc/inittab, run init q to stop any getty process that may currently be running on the port.

The cu command uses the /usr/lib/uucp/Devices file to get the information it needs about the device to use when establishing the connection. Here is an entry in the Devices file for a Hayes 2400 baud modem attached to tty0:

ACU tty0 - 2400 hayes

Here is an example of a minimal cu command line that specifies a telephone number:

cu 4155551212

When a telephone number appears on the cu command line, cu searches the Devices file for an entry that begins with ACU. Since we set up the Devices file with a line that starts with ACU, it will attempt to dial through serial port 0 (modem) at 2400 baud.

NOTE: The A/UX Network System Administration manual chapter on "Setting Up the UUCP System" contains complete descriptions of the procedures outlined above.

A/UX: How to Login via a Serial Port (9/94)

How do I login via a serial port?

This article has been archived and is no longer updated by Apple.
1) With the power to the system off, connect a straight-through serial cable from your A/UX system to the terminal or system that will be acting as a terminal.

2) Boot A/UX to multi-user mode. To put the system into multi-user mode, you can either type "init 2" at the command line or edit the file /etc/inittab to change default run level from "s" (single user mode) to "2" (multi-user mode).

3) Start a getty on the port used for login. Do this by editing one of the bottom two lines in /etc/inittab. One line changes the settings for the modem port, while the other one changes the settings for the printer port. The default entry for the modem port reads:

00:2:off:/etc/getty tty0 at_9600 # Port 0 (modem); set to 'respawn'

Change the word "off" to "respawn, so that it looks like:

00:2:respawn:/etc/getty tty0 at_9600 # Port 0 (modem); set to 'respawn'

Apple IIGS: VCR Connection

This article has been archived and is no longer updated by Apple.

Here's how and why to connect your Apple IIGS to a VCR.

How: use a normal Apple IIGS video cable to connect the Apple IIGS's video output to the VCR's camera input. (Video cables are available in several lengths.) Set the VCR to "camera."

Why: This arrangement lets you use the television that's connected to the VCR as a computer monitor -- and you don't have to use an RF modulator. Because the VCR thinks the computer is a camera, you can save whatever the computer displays on video tape. Use a drawing program, for example, to make title screens for your live-action videos, or use an animation program to make your own cartoon videos.

A/UX: How to Do Remote Printing (9/94)

How can I do remote printing?

This article has been archived and is no longer updated by Apple.
On A/UX 2.0

You can run remsh, using cat in the local system and lp through the remote shell on the system where the printer is connected. Here is an example in which "mysys" is the host name:

cat file1 | remsh mysys lp

On A/UX 3.0

The operating system recognizes remote printer indications in the file /etc/printcap. /etc/printcap contains configuration information used by the lpr print spooler. If you plan to connect a printer directly to a remote computer on the network, a user on the local Macintosh can print on that printer by using the -P remotehost option to lpr if the /etc/printcap file on the Macintosh is set up. Edit the file /etc/printcap and find these lines:

Remote UNIX line printer

Change 'RemoteHost' to actual name of the remote UNIX host

remote|remote line printer:\\

:lp=:rp=lp:rm=RemoteHost:sd=/usr/spool/lpd/Remote:

Change RemoteHost to the host name of the computer to which the printer is directly connected.

A/UX: The /etc/exports File

Article Change History

08/31/92 - REVIEWED
*For technical accuracy

What's the file /etc/exports used for? What is its format?

This article has been archived and is no longer updated by Apple.
NFS file servers use the /etc/exports file to control which file systems can be mounted by which systems on the network. Entries in /etc/exports specify a file system name that can be remotely mounted. The file system name is left justified and may be followed by a list of hostnames or netgroup names separated by spaces or tab characters.

If a hostname or netgroup name follows the file system name, export permissions are limited to the host(s) or netgroup(s) specified. Otherwise, it is open to everyone.

A number sign (#) anywhere on a line begins a comment that remains in effect to the end of the line.

An example /etc/exports file could look like:
/
/usr/catman my_system_name

In this example, the "/" partition is exported to any system on the network. The "/usr/catman" partition, however, is only exported to the system named "my_system_name".

A/UX: How to Determine Which Partitions Are Being Exported

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

How do I find out which partitions are being exported from another system on the network?

This article has been archived and is no longer updated by Apple.
By using the "-e" options with the /usr/etc/showmount command and specifying a hostname, you can get a list of the partitions that are being exported from another system on the network.

For example, to get a list of exported directories from the system "macaux," enter the line:

showmount -e macaux

The output could look like this:

export list for macaux:
/s1 everyone
/ everyone

This output tells us that the "/" and "/s1" directories from the system "macaux" are being exported to everyone.

Pascal III: Comparison to Apple II Pascal (1 of 2)

This article has been archived and is no longer updated by Apple.
The majority of Apple II Pascal programs can be recompiled then executed on the Apple III without modification. The following is summary of significant differences between Pascal II and Pascal III. Please refer to the Apple III Pascal Programmer's Manual, Volume 2, starting on page 128, for additional information.

OTHERWISE Clause in CASE Statement:

Pascal III provides an OTHERWISE clause in the CASE statement. The OTHERWISE clause allows you to enter a statement that is executed if none of the cases are executed. Refer to chapter 5 of the Apple III Pascal Programmer's Manual.

SOS Pathnames:

SOS Pathnames are different from the Pascal filenames used on the Apple II. Pascal III supports both types of names, as explained in the Apple III Pascal Introduction, Filer, and Editor manual.

SOS Device Driver Support:

Pascal III supports SOS device drivers as "I/O units." See Chapters 10 thru 12 in the Standard Device Drivers Handbook.

Graphics:

The Apple III screen graphics modes driven through the SOS graphics driver differs significantly from the Apple II. Therefore, a new unit named PGRAF is supplied as a high-level interface to the graphics driver. Refer to the Standard Device Driver manual for additonal information on the SOS graphics driver.

Turtlegraphics is available only for compatibility with the Apple II. Refer to Appendix K of the Apple III Pascal Programmer's Manual.

New Procedures:

The AppleStuff unit contains Date, TimeOfDay, ClockInfo, and SetTime procedures for reading and setting the Apple III system's internal date and time. See Appendix D of the Apple III Pascal Programmer's Manual.

New Data Types:

The ByteStream and WordStream types are provided for use as types of Var parameters in procedure and function definitions. See Chapter 3 of the Apple III Pascal Programmer's Manual.

Real Arithmetic:

For operations on type Real values, Pascal III conforms to the IEEE floating-point standard. Under default conditions, the difference between the Pascal III and Apple II Pascal is invisible, unless the program performs operations giving exeception results, such as division by zero. See Appendix F of the Apple III Pascal Programmer's Manual for complete details.

The Apple Pascal Numeric SANE package, available for both the Apple II and Apple III, establishes a universal mathematic environment for the two systems.

Library Files and Units:

Each Pascal III codefile can have a "program library" file associated with it in addition to the System.Library file. Thus, library units are more convenient; furthermore, programs may have up to 48 segments at run time.

When compiling a unit, it is no longer necessary in all cases to use the Compiler's swapping option.

Published Date: Feb 18, 2012

A/UX: How to Print a List of Exported File Systems

How do I print a list of exported file systems?

This article has been archived and is no longer updated by Apple.
By using the "-e" option with the /usr/etc/showmount command, you can quickly list the directories you have exported to other systems on the network.

Example output from the command line "showmount -e" executed the command line from the system "my_system_name":

export list for my_system_name:
/users machen redpony
/ machen redpony

This example says that the directories "/" and "/users" are exported to the systems "machen" and "redpony" only.

In A/UX 3.0, /etc/exportfs can be used. With no options, all exported file systems are listed.

Published Date: Feb 18, 2012

A/UX: How to Monitor NFS Activity (9/94)

How can I monitor NFS activity?

This article has been archived and is no longer updated by Apple.
The nfsstat command displays or initializes information about the Network File System (NFS) and Remote Procedure Call (RPC) interface to the kernel. It is a good way to monitor NFS activity and load.

The nfsstat command executed without any options gives you a complete output, displaying the NFS, RPC, server and client statistical information.

TA44869_AUX_The_nobody_Login_Account__(TIL06304).pdf

A/UX: The "nobody" Login Account (9/94)

Article Last Reviewed: 6 September 1994

How do I modify /etc/passwd for NFS? What's the "nobody" login account for?

This article has been archived and is no longer updated by Apple.
The /etc/passwd file must contain a login account for "nobody".

Enter the line: grep nobody /etc/passwd

The response should be:

nobody:*:65534:65534::/:

If this line does not appear, modify the /etc/passwd file to include it. This account is used by NFS to disallow root access via NFS.

For system security reasons, the super-user does not have access permissions on remote file systems. This is implemented by mapping UID 0 ("root") to UID 65534 (unsigned representation of -2 in 2's complement notation) on all NFS client systems. The super-user on an NFS client has the same permissions as a user with the UID -2.

The login account "nobody" has the UID 65534 (-2).

A/UX: Fields in /etc/fstab (9/94)

What are the fields in the file /etc/fstab?

This article has been archived and is no longer updated by Apple.
The file /etc/fstab consists of a number of lines like:

/dev/dsk/c0d0s0 / 5.2 rw 1 1
hostname1:/usr/catman /usr/catman nfs ro,soft 2 2

Fields are separated by blanks or tabs. A number sign (#), as the first non-space character, begins a comment.

The first field in each line specifies the device on which the local partition to be mounted exists. For a remote file partition, it contains the hostname of the system on which the remotely-mounted file system really exists, and then a colon (:), followed by the absolute path name of the file partition as it exists on the server system.

The second field is the local mount-point. For a local system file partition, the device pathname is specified. For a remote file partition, you should see the remote host's name and the full pathname of the file partition to be mounted.

The third field is the type of file system. This may be 4.2, 5.2, nfs, or ignore. If this field is ignore, the entire line is ignored. This feature lets you keep remote mounts that you do not want to mount routinely in /etc/fstab when you boot the system.

The fourth field contains options that are passed to the mount command. Some of the valid options include:

- "rw" specifying that the mounted file system is readable and writable.

- "ro" specifying that the mounted file sytem is read-only.

- "soft" If a file system is mounted read-only, this option lets the client system keep running using only local data, when the server system goes down.

The fifth field is a dump-level parameter used by the dumpfs command.

The last field is the fsck pass number; this number indicates in what order the partition will be checked by fsck. Partitions on different physical drives may be checked at the same time. This field value is not used on remote file systems.

A/UX: Solution to "RPC_PROG_NOT_REGISTERD" Error

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I tried to mount a remote file system and got the error:

mount: <hostname> server not responding: RPC_PROG_NOT_REGISTERD

This article has been archived and is no longer updated by Apple.
Check to see that the /etc/initd daemon is running.

1) Log on to the system as "root".

2) Enter the line:

ps -ef| grep mount

The output should look like this:

root 317 107 0 Apr 25 ? 0:05 rpc.mountd

If you did not get this output, do these steps:

1) Enter the line:

grep inetd /etc/inittab

You should see this output:

net9:2:respawn:/etc/inetd

The inetd daemon starts the rpc.mountd daemon. If the output does not match the above output, edit the file /etc/inittab and change that line so that it does.

2) Shut the system down into single-user mode;

sync; sync
init 1.

3) Bring the system back up into multi-user mode

init 2

A/UX: Solution to "mount: no such file or directory"

I'm trying to mount a file system and keep getting the error:

mount: <file system> no such file or directory

This article has been archived and is no longer updated by Apple.
Be sure that the file system you specify really exists.

1) Is the file system pathname spelled correctly?

2) Is the directory pathname you specified actually there?

Published Date: Feb 18, 2012

A/UX: Solution to "mount: not in export list for " Error

I tried to mount a file system and got the error:

mount: not in export list for <host>

This article has been archived and is no longer updated by Apple.
Enter the line:

showmount -e

followed by a space and the name of the of the host from which the file system you are mounting exists.

The output displayed lists all the file systems that the remote host has exported and to which systems it has exported them.

Here is example output from the command line, "showmount -e macaux":

export list for macaux
/cmd/src everyone
/s1 my_system_name sleepy grumpy

In this example, "my_system_name", "sleepy", and "grumpy" systems have permission to mount the file system "/s1". No other system has permission. However, "/cmd/src" can be mounted remotely by any system on the network.

If the name of your system is not included in the export list for a particular file system, you cannot mount that file partition. Consult with the system administrator of that host to have your system added to the export list.

Here is another example output from the command line, "showmount -e macaux":

export list for macaux
/cmd/src everyone
/s1 my_system_name sleepy mispeled

In this example, "my_system_name", "sleepy", and "mispeled" systems have permission to mount the file system "/s1". No other system has permission. However, "/cmd/src" can be mounted remotely by any system on the network.

The system "misspelled" is not spelled correctly in the export file, so that system cannot mount that partition. Consult with the system administrator of that host to have your system correctly spelled in the export list.

Published Date: Feb 18, 2012

A/UX: Solution to "network unreachable" Error

I tried to mount a remote file system and got the error:

network unreachable

This article has been archived and is no longer updated by Apple.
This could be because the Ethernet card or cable connection is not working correctly. Here are four trouble-shooting steps:

1) Make sure that the Ethernet cable from the Ethernet card to the rest of the network is connected and seated properly and snugly.

2) Check that there is not a broken connection in the main network cable itself.

3) Check that cables do not show any physical signs of damage. Ethernet cables should not be crimped, bent, or squished.

4) Replaced all cables that show excessive wear.

Pascal III: Comparison to Apple II Pascal (2 of 2)

This article has been archived and is no longer updated by Apple.

Memory Organization:

An Apple III operating SOS or Pascal has different memory organization than when running Apple II Pascal. The amount of memory available is somewhat greater on the 128K Apple III than on the Apple II.

Memory organization could effect an Apple II program run on a Apple III, if the program depends on pointer values created when running on an Apple II and stored on a diskette.

Similarly, an Apple II program that depends on specific Apple II hardware addresses does not work on the Apple III. This could for example affect Apple II Pascal programs designed to drive the Silentype printer; though such programs could be revised to use the Apple III Silentype driver described in the Standard Device Drivers Handbook.

The UNITSTATUS Procedure:

The UNITSTATUS procedure is supported for device oriented I/O. See Chapter 12 of the Apple III Pascal Programmer's Manual.

Runtime Segment Table:

The runtime segment table allows for 64 segments instead of 32. See Chapter 15 of the Apple III Pascal Programmer's Manual.

Conditional Compiling:

The Apple III Pascal Compiler allows conditional compilation. See Appendix F of the Apple III Pascal Programmer's Manual.

CHAINSTUFF Unit:

Since Apple III Pascal has no "system swapping" mode, the SWAPON and SWAPOFF procedures are absent from the CHAINSTUFF unit.

Compiling Apple II Code:

The Pascal III compiler can compile code to run on the Apple II. Refer to Appendix F of the Apple III Pascal Programmer's Manual.

File Variable Size:

Every declared file in an active procedure requires 1,100 bytes of memory.

Compiler Options:

Option names can be spelled out.

Because Compiler options always end with a comma, all can be chained together except for the Include option. The Comment option cannot contain a comma and the Resident option does not accept a list.

Procedure Complexity:

The Apple III larger memory supports more complex code than the Apple II.

System Globals:

Users of the {$USER-} option may find that their programs are not portable.

A/UX: Solution to "mount: : Not owner" Error

I tried to mount a file system and got the error:

mount: <directory>: Not owner

This article has been archived and is no longer updated by Apple.
You must be logged in as "root" when mounting partitions.

Enter the line:

whoami

The output should be: "root". If it isn't, log in as "root" and try the mount again.

Published Date: Feb 18, 2012

A/UX: "NFS server not responding..." Error (9/94)

I tried to mount a file system and got the error:

NFS server <hostname> not responding, still trying

This article has been archived and is no longer updated by Apple.
Check to see that the remote system (the one with the file system you're trying to mount) is available.

Enter the line:

ruptime

Here is an example of the kind of output you might see:

grumpy down 0:11
sleepy up 36+00:41
snow up 21:54

The system "grumpy" is down. Because the host is down, the NFS file systems aren't available and won't be available until the host comes back online.

A/UX: How to Make an NFS Daemon Run (9/94)

My NFS daemon isn't running. Why not?

This article has been archived and is no longer updated by Apple.
Was the nfs daemon started in /etc/inittab? If not, follow these steps:

1) Log on as "root".

2) Edit the file /etc/inittab

3) Change the line

nfs3:2:off:/etc/nfsd 4 # set to "wait" for NFS server

to:

nfs3:2:wait:/etc/nfsd 4 # set to "wait" for NFS server

4) Enter the line: telinit q

5) Enter the line: ps -ef | grep nfsd (or, ps-a | grep nfsd in the C shell)

The output should resemble the following:

root 93 1 0 10:00:34? 0:00 /etc/nfsd 4
root 94 1 0 10:00:35? 0:00 /etc/nfsd 4
root 95 1 0 10:00:35? 0:00 /etc/nfsd 4
root 96 1 0 10:00:35? 0:00 /etc/nfsd 4

Note that the numbers in the columns may differ on your system.

TA44879_AUX_NFS_Defined__(TIL06313).pdf

A/UX: NFS Defined (9/94)

What is NFS?

This article has been archived and is no longer updated by Apple.
NFS is the abbreviation for "Network File System".

NFS lets UNIX systems, connected by an Ethernet network, share file systems or partitions remotely (that is, over the network); it lets one UNIX system on the network share and access the disk space of another system on the network. This helps conserve disk space and allows the sharing of resources. For example, printers, or the on-line manual pages are often placed on an NFS volume for global access by everyone on the network.

An NFS client (the remote system) may mount a file partition of the NFS server (the system on which the actual disk space for the partition exists). This is all transparent to the user. The user can access the remote file system as though it were a local disk.

A/UX: Solution to "/etc/fstab: No such file or directory" Error

I tried to mount a file system and got the error:

/etc/fstab: No such file or directory

This article has been archived and is no longer updated by Apple.
The name of the file system that you are trying to mount does not exist in the file /etc/fstab.

1) Log onto the system as "root".

2) Edit the file /etc/fstab.

3) Add an entry for the file system that you are mounting.

Published Date: Feb 18, 2012

A/UX: Solution to "mount: already mounted" Error

I tried to mount a file system and got the error:

mount: <file system> already mounted

This article has been archived and is no longer updated by Apple.
Follow these steps:

1) Log onto the system as "root".

2) Enter the line: mount

A list of the currently mounted file systems will be displayed.

Example output:

/dev/dsk/c0d0s0 on / type 5.2 (rw,noquota)
/dev/dsk/c0d5s0 on /users type 5.2 (rw)
macaux:/s1 on /earlw1 type nfs (rw,soft)

If the file system you trying to mount is listed, then it is already mounted. You may unmount the file system and mount it again to be sure.

1) Enter the command

umount

followed by a space and the absolute pathname of the file system directory. For example, the command "umount /users" unmounts the /user partition.

2) Enter the command

mount

followed by a space and the device name of the file system to be mounted, a space, and the absolute pathname of the directory on which the file system will be mounted. For example, the command

mount /dev/dsk/c5d0s0 /users

mounts the file system associated with the device "/dev/dsk/c5d0s0" on the directory /users.

LaserWriter IINTX: Dual Connection to Macintosh and PC

Is it possible to connect a LaserWriter IINTX (with rev 2.0 ROMs) to a Macintosh, through an AppleTalk connection AND to an IBM PC, through a serial connection?

I want to have both cables connected at the same time and select the appropriate port to print from. How do I change from HP LaserJet mode to PostScript mode without changing the DIP switches?

Can I simultaneously have a serial connection and an AppleTalk connection with a LaserWriter IINTX?
This article has been archived and is no longer updated by Apple.
The LaserWriter IINTX will not support simultaneous serial and LocalTalk connections. We recommend that if you are switching between both kinds connections you should disconnect the cable you're not using.

However, it is possible to connect a LaserWriter to an AppleTalk network and to an IBM PC, using software switching to change between the two.

- You must have the LaserWriter IINTX ROM upgrade to switch both ways.
- The following instructions assume that there is a LocalTalk connection to the LaserWriter through the RS-422 port, a serial connection to the IBM PC through the RS-232 port, and all DIP switches are up (default AppleTalk PostScript).
- Remember that the LaserWriter will need some time to respond to the procedures outlined below. Its Ready light flashes while the LaserWriter is setting each of these parameters. Wait for this light to stop flashing before you send another command, or the LaserWriter may not receive all of the next command.

Caution: If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

To Switch From an AppleTalk Connection To a Serial Connection

Step 1
To disable the RS-422 port, set its baud rate to 0. Send this PostScript file to the LaserWriter:

```
%=========================================================
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
9 0 0 setsccbatch
9 0 0 setsccinteractive
<Control-D> %(if in interactive mode)
%
% end PostScript Code
%=========================================================
```

This prevents the printer from sending serial information over the AppleTalk network, causing unpredictable results.

Step 2
To set the LaserWriter to work in LaserJet Plus mode through the serial (RS-232) port, send this PostScript file to the LaserWriter:

```
%=========================================================
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
5 setsoftwareiomode
0 sethardwareiomode
<Control-D> %(if in interactive mode)
%
% end PostScript Code
%=========================================================
```

The LaserWriter now uses the RS-232 port, as if it were a LaserJet Plus. The LaserWriter no longer understands PostScript, is not available over the network, and does not appear in the Chooser.

But the IBM PC can now talk to the LaserWriter. To confirm this, type this command at the DOS prompt:

```
MODE COM1:96,n,8,1,p
```

This tells the IBM PC to send information at 9600 baud, the default for the LaserWriter through the serial port. You can now print as though you were connected to a LaserJet Plus.

To Return To a PostScript LaserWriter Over an AppleTalk Network

Step 1
Send a file containing the characters Escape, Delete, 0, and Control-D. The best way to do this is to use BASIC to explicitly put these characters in a file. For example, use this BASIC program:

```
open "psreturn.txt" for output as #1
print #1,chr$(27);chr$(127);"0";chr$(4)
close #1
```

and send this file to the LaserWriter using this command from the DOS prompt:

```
TYPE PSRETURN.TXT > COM1
```

whenever you want to switch to a PostScript LaserWriter.

The LaserWriter is now in PostScript mode and using serial communication. You can send PostScript programs from the IBM PC through the RS-232 port, and the LaserWriter will respond.

To Switch Back to AppleTalk Communication Through the RS-422 Port

Step 1
At the DOS prompt, create this PostScript program:

```
COPY CON SET.MOD
%============================================================
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
0 setsoftwareiomode
2 sethardwareiomode
<control-Z>
%
% end PostScript Code
%============================================================
```

Step 2
Send the program to the LaserWriter with the DOS command:

```
TYPE SET.MOD > COM1
```

(this will take some time).

The LaserWriter is now back in AppleTalk PostScript mode, using the RS-422 port.

Step 3
Set the baud rate of the RS-422 port back to what it was. This can be done from your Macintosh using this PostScript program:

```
%============================================================
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
9 9600 0 setsccbatch
9 9600 0 setsccinteractive
%
% end PostScript Code
%============================================================
```

This assumes that you want to set the baud rate to 9600. Change this number if you want another rate.

This is not the LocalTalk baud rate; it is the baud rate that would be used if you connected serially to the RS-422 port. You are not required to set this number back to what it was to work over LocalTalk, but it is the default number set in the printer.

The LaserWriter's settings should now be what they were when you started.

MacTerminal 3.0: How To Send "Break"

A customer wants multisession support from MacTerminal 3.0 running on a Macintosh connected to a DEC terminal server. He needs to be connected to the LocalTalk network to print during sessions.

His terminals let him use a "break" key to switch between different sessions that the terminal server is maintaining for the particular terminal.

He wants to be able to watch three sessions at the same time in different windows on a two-page display.

What is the ASCII code to put a DEC terminal server into a new session?

This article has been archived and is no longer updated by Apple.
There is no ASCII code for the BREAK signal. The data line can be in two conditions:
- MARK (negative voltage, binary 1), or
- SPACE (positive voltage, binary 0).

The data line is normally in MARK condition; it is in the SPACE condition only while a frame is being transmitted. A longer-than-normal SPACE condition, around 100 to 600 milliseconds, is used as a special signal known as a BREAK.

The "Send Break" command in MacTerminal 3.0 sends a long break (3.5 seconds) across the open connection, which has the same effect as choosing the corresponding Break key from the keyboard. The "Send Break" command in MacTerminal 3.0 is under the Sessions menu; its keyboard equivalent is Command-Y.

A/UX: How Users Can Shut Down Without Root Access (9/94)

A system administrator at an A/UX site wants to give users the ability to power off their machines, but without giving them root access. Is the following procedure a suitable way to power down the machine? Here is what he did:

1) He modified the /mac/bin/Login file with ResEdit, changed the string
Guest to poweroff (STR# resource), and modified the dialogs accordingly.

2) He compiled the following C program and named the executable poweroff:

poweroff.c

```
#include <stdio.h>

main(argc, argv)
int argc;
char *argv[];

{
setuid(0);
argv[0] = "reboot";
execl("/etc/reboot", "reboot", "-h", 0); /* -- run reboot */
/* -- NOTREACHED */
}
```

3) Poweroff* was put in the /root directory and given these permissions:

```
# ls -l /root/poweroff
-rwsr-xr-x 1 root root 2373 Aug 17 18:20 /root/poweroff
```

4) An account called "poweroff" was added to /etc/passwd that executes
/root/poweroff when a user logs in under that name (or selects the
power-off radio button in the Login screen). For example:

```
# grep poweroff /etc/passwd
poweroff::8:1000:user shutdown account:/root:/root/poweroff
```

The only possible problem with this is that a user could log on to another user's machine and shut it down. Giving the user a power-off password makes this unsuitable for installations where there is limited network discipline.

This article has been archived and is no longer updated by Apple.
Your C code seems to meet the customer's need: shutting down A/UX without being root.

This additional code can be included in the poweroff.c to prevent a remote user from shutting down the system:

```
char *ttyname();
char *p;
char *d="/dev/ttyC";

p=ttyname(0);
if (strncmp(p, d, 9) != 0) {
fprintf(stderr, "%s: not a CommandShell type of window\\n", argv[0]);
exit(1);
}
```

TA44887_LaserWriter_No_Backup_Utility_for_NonComposite_Fonts_(TIL06321).pdf

LaserWriter: No Backup Utility for Non-Composite Fonts

The documentation with the LaserWriter IINTX I/O board revision 3.0 upgrade tells users to back up the fonts stored on a hard disk connected to the LaserWriter IINTX before doing the upgrade. How do I make a backup of the fonts disk?

This article has been archived and is no longer updated by Apple.
At present, there are no utilities specifically for backing up fonts stored on a LaserWriter hard disk.

Before installing the ROM upgrade, use the LaserWriter Font Utility (it comes with the LaserWriter IINTX) to reformat the hard disk. After installing the ROM upgrade and restarting the system, re-install fonts from the original floppy disks. (If you purchased your fonts from Adobe, already installed on a hard disk, contact Adobe for the procedure.)

Composite fonts are an exception: with the new version of the LaserWriter Font Utility (version 2.0.1, shipping with upgraded printers), you can back up composite fonts to floppy disks. (Composite fonts are small fonts hooked together to support Kanji and Chinese characters, which require more than the 256 characters supported in a single PostScript font.)

LaserWriter: Printing Non-PostScript Files from a PC

Some customers report problems printing to a PostScript LaserWriter from MS-DOS PCs equipped with LocalTalk PC Cards. From the PC, the printer appears in the Chooser and can be selected -- but it won't print such files as AUTOEXEC.BAT.

This article has been archived and is no longer updated by Apple.
The problem may be that the LaserWriter was connected for use with PostScript files instead of plain text files. When AppleShare PC connects to a LaserWriter for PostScript use, it sends the raw data directly to the LaserWriter without modification. This doesn't work for typical DOS text files because they aren't in PostScript format.

The Epson emulation mode accepts standard text files and converts them to PostScript format before sending them to the LaserWriter. This is the mode you should use for printing AUTOEXEC.BAT and other non-PostScript files created by applications that support PostScript printing.

For most users, the best way to set up AppleShare PC is to make two connections to the LaserWriter: one for PostScript and the other for plain text. For instance, use LPT2 as the Epson connection and LPT3 as the PostScript connection. This uses slightly more conventional memory, but it allows you to print either type of document without altering configurations.

Ethernet: DDP Client With DDP Type=69 ID

While checking Ethernet traffic, we noticed a large number of short (60-byte) EtherTalk packets (Phase 1) of an unknown protocol type. We opened the packet and found that they were DDP Type=69. The Ethernet is heavily loaded, especially with LAVC (Local Area VAX Cluster) traffic, and the apparently exclusive use of minimum size packets is a concern.

Can you identify the application that uses/produces these packets? We use 3COM servers and the older 3+Share Macintosh client software.

This article has been archived and is no longer updated by Apple.
There is no way to tell which vendor creates packets with DDP Type=69 because Apple does not assign or control the use of DDP Type beyond $0F.

We don't know if the packets come from the 3COM server, but you could try to find the Ethernet node by matching the 48-bit Ethernet source address in the 802.3 header and the Ethernet adapter hardware address.

MultiGate Mac: General Information

MultiGate Mac is a software router/gateway for Macintosh II computers from Network Resources Corporation. It supports

* AppleTalk and TCP/IP routing

* IP in DDP encapsulation (MacIP support for MacTCP clients)

* Up to five Ethernet cards and one LocalTalk.

This article has been archived and is no longer updated by Apple.
MultiGate Mac can run as a concurrent AppleShare application, or under MultiFinder or System 7 with a mail gateway. The only requirement is that an additional Ethernet card be used for other services besides the gateway, because MultiGate Mac requires dedicated cards for routing.

MacIP support lets MacTCP clients on LocalTalk access TCP/IP host computers. MultiGate Mac can be used to connect an AppleTalk internetwork to a TCP/IP backbone and provide IP in DDP encapsulation for up to 254 Macintosh computers anywhere on the AppleTalk internetwork. Flexible IP support allows for static addressing via MacTCP, MacTCP server mode, or a combination of the two.

MultiGate Mac also supports an alternative host access scheme, based on the MultiGate Stream Protocol. This user-friendly protocol is highly efficient on limited-bandwidth networks (LocalTalk, for example).

MultiGate Mac supports full TCP/IP interior gateway routing between Ethernet segments. This includes support for RIP, proxy-ARP, and RFC-950 subnetting. SNMP support is also provided.

Configuration

ConfigureIt!, a HyperCard stack, makes it easy to configure the gateway. ConfigureIt! builds a text file that is read by the gateway at startup. (This file can also be edited using TeachText.)

When MultiGate Mac reads the configuration file, it does extensive error checking to make sure the configuration is valid. It checks for syntax errors in the configuration file, and when the network protocols are initialized, it checks for such items as valid network numbers, consistent subnet masks, duplicate addresses, etc. If it detects an error, the gateway logs a message to the monitor, detailing the problem. The user can then correct the problem and try again.

Once the gateway is running, it continues to monitor the network. It shuts down only if it encounters a serious network error. In such a case, it logs a message to the monitor.

Operations Interface

A password-protected Operations Interface is accessible via any computer capable of establishing a Telnet session. This powerful interface provides detailed information on gateway status, port statistics, and gateway configuration. It also provides detailed network information, including AppleTalk routing information, with statistics on network usage, IP routing, encapsulation mapping tables and activity, ARP and AARP tables, "pinging" of AppleTalk or IP devices, tracking and logging of network error packets, and so on.

The error tracking feature is useful for isolating network faults; it lets the user view the first 100 bytes of each protocol layer in an error

packet that has been saved. This information can be used to pinpoint the offending entity. Over 100 network errors on the AppleTalk and IP networks are tracked.

Features of the Telnet Interface
---

* Prints AARP tables (AT->EN mapping tables).

* Prints ARP tables (IP->EN mapping tables).

* Prints the gateway configuration.

* Evaluates expressions in octal, decimal, and hex.

* DNS lookups of names.

* Can dump specific portions of router memory (like MacsBug).

* Prints a summary of various errors and events recorded by the router including: packets dropped due to unknown AT network, packets dropped due to unknown EN address (via AARP), hop count overflow, error packets saved by router. Over 100 types of error packets are saved. The first 100 bytes of each protocol layer can be dumped for analysis to determine originating device, destination, type of packet, etc. Many events other than those listed above are recorded by the gateway.

* Logs errors to your screen in real time.

* Can define the format packets are logged with.

* Can log packets to/from a given address of given type in real time.

* Can shut down the gateway.

* Dumps address mapping for IP-in-DDP encapsulation.

* Prints summary of each TCP<->MSP connection.

* Prints the detailed state of a specific connection.

* Dumps the entire AT<->IP mapping tables.

* Dumps NBP address tables.

* Does an NBP lookup and prints the results.

* Dumps info about packet buffer at a given address.

* Sends and times Echo packets to the named host (AppleTalk or IP).

* Can restart the gateway.

* Dumps the RTMP tables for all AppleTalk nets.

* Dumps the RIP tables for all IP nets.

* Gives the RTMP or RIP entry for a defined network#.

* Prints the status of the gateway and detailed statistics on each port.

* Traces connections.

* Displays current software version.

* Flushes the ARP/AARP entry for a particular address.

* Dumps the RTMP table for each net in that zone.

Security

The current version of MultiGate Mac provides the following:

* Filtering of inbound Telnet sessions to connected networks

* The ability to declare a network insecure. This means that the gateway won't respond to RTMP tables and RIP tables on a given network, unless the router providing the tables is statically configured in the gateway configuration file.

MultiGate 2000

The functionality of MultiGate Mac is also available with NRC's dedicated LocalTalk-to-Ethernet hardware router, MultiGate 2000. The software module, called IPGate, provides all the features of MultiGate Mac other than Ethernet-to-Ethernet routing. Instead of logging start-up errors to the screen, IPGate logs them to NVRAM and then reboots from PROM code (ensuring that the router will come back up). MultiGate Manager Jr. can then be used to retrieve the error code from NVRAM. Users can then analyze the error, make the appropriate corrections to the router configuration, and then download a new image to the router.

For more information, search on "Network Resources".

Macintosh IIci: Built-in Video Memory Usage

I have a problem with a Macintosh IIci with 1MB of RAM, which allows only the Black/White option in the control panel -- even though the monitor is RGB. Is there a way to increase the RAM video to allow using 256 colors?

This article has been archived and is no longer updated by Apple.
A Macintosh IIci system with 1MB RAM supports up to 256 colors or grays, using RAM-based video (RBV). This chart details how much memory is used:

2 Colors/Grays (1-bit) 64K
4 Colors/Grays (2-bit) 96K
16 Colors/Grays (4-bit) 160K
256 Colors/Grays (8-bit) 320K

A 1MB Macintosh IIci system using 8-bit video would, in effect, be a 704K system. This is not recommended, because it doesn't leave much memory for the System software and application programs.

A 1MB Macintosh IIci system defaults to 64K of memory allocated for video. A Macintosh IIci system with more than 1MB defaults to 320K of memory allocated for video.

Here's how to adjust the amount of memory allocated to video:

1) In the Control Panel, select the Monitors CDEV.

2) Hold down the Option key. The icon that represents the built-in video will contain a very small Macintosh in addition to the monitor number.

3) Click on the "Options..." button.

The setting in the top half of the dialog allows the user to select the gamma table that is to be used to compensate for phosphor luminosity characteristics of specific monitors. This setting is not unique to the Macintosh IIci and has nothing to do with the amount of memory that is allocated to video RAM.

The bottom half of the dialog, labeled "Memory Allocation For Built-In Video", contains the radio buttons for setting how much memory is allocated to video. This setting limits the maximum number of colors/grays that will be supported.

A/UX 2.0: How To Turn Off 32-Bit Clean Warning Message

How do I remove the 32-bit clean warning that appears when I launch an application? I know A/UX checks a certain bit within the application, but I don't know which one.

This article has been archived and is no longer updated by Apple.

```
In A/UX 2.0, there are two ways to set the bit:

* From an A/UX CommandShell window, issue the command:

 /mac/bin/changesize +32BitCompatible 'Pathname:Application'

 For example:

 /mac/bin/changesize +32BitCompatible 'MacPartition:MS Word:Microsoft
  Word'

* From A/UX MultiFinder Desktop, open the Macintosh application with the
 ResEdit program, open the SIZE resource, look for the "32 Bit
 Compatible" flag, and set it to 1.
```

AppleCD SC: Device Driver Status Calls

My questions concern the AppleCD SC's SCSI driver. In my application (written in C), I do a Status Call #98 (called GET SIZE). I receive back 11 words (22 bytes):

08 00 00 4A DA
23 00 3C 85 C8
00 4A F9 B8 20
00 00 4B 01 1A
20 24

1) Is this the standard size to be returned by this call?

2) Is there a minimum and maximum size?

3) What is the format of this response?

This article has been archived and is no longer updated by Apple.
The information you're looking for is in the AppleCD SC Developer's Guide, available from APDA. It describes all of the device driver Status calls for the AppleCD SC, including the inputs and the outputs for each Status call.

In response to your specific questions about Status call 98 (GetSize):

1) The default block size is 2048 bytes.

2) The legal block sizes (in bytes) for the AppleCD SC driver are:
512, 256, 1024, 2048, 2336, and 2340

3) The GetSize Status call will return in scParam + 0 the currently assigned logical block size of the AppleCD SC. In other words, in the first two bytes (one word) it returns the logical block size, which by default is 2048.

In your example, the first two bytes are 08 00. 0800 in hex translates to decimal 2048 -- the default size set for the AppleCD SC. The remaining 20 bytes are not used for this call.

HyperCard 2.0: "Link to" Problem on 68000-Based Systems

I'm having a problem with HyperCard 2.0. I get an ID=02 bomb when I do the following:

Create a new stack.
Create a new button.
Use "Link to" to link the button to this card.
Use "Link to" to link the button to this card.

It's the second LinkTo function that causes the bomb.

This article has been archived and is no longer updated by Apple.
This is a known problem that seems to occur only on 68000-based Macintosh systems.

As a workaround, delete the line "go to card xxxx" from the button's script before modifying the link.

A/UX: Solution to "/etc/mtab: No such file or directory" Error

Article Change History

08/31/92 - REVIEWED
*For technical accuracy

I tried to mount a file system and got the error:

/etc/mtab: No such file or directory

This article has been archived and is no longer updated by Apple.
(A) Check for /etc/mtab. The file /etc/mtab must exist for the mount command to work.

1) Log onto the system as "root".

2) Enter the line, "ls -l /etc/mtab".

The output displayed should look like this:

-rwxr-xr-x 1 root sys 147 Apr 25 14:07 /etc/mtab

The size and modification date of this file will differ on your system.

If the output is "/etc/mtab not found", then, the file /etc/mtab is missing and must be created. This series of command lines will create the file /etc/mtab with the correct permissions and ownerships:

1) Enter the line: touch /etc/mtab

2) Enter the line: chgrp sys /etc/mtab

3) Enter the line: chmod 755 /etc/mtab

(B) Check Permissions on the file /etc/mtab.

Incorrect permissions on the file /etc/mtab could cause this error.

1) Log onto the system as "root".

2) Enter the line: ls -l /etc/mtab

The output displayed should look like this:

-rwxr-xr-x 1 root sys 147 Apr 25 14:07 /etc/mtab

The size and modification date of this file will differ on your system.

3) If the first column of the output displayed does not equal:

-rwzr-xr-x

enter the line: chmod 755 /etc/mtab

This will correct the file permissions.

Macintosh Plus: SCSI Device and Driver Support Limits

How many SCSI drivers does the Macintosh Plus support according to Apple's specifications? Are there any restrictions on the type or nature of those drivers?

This article has been archived and is no longer updated by Apple.
There are no "published" specifications regarding how many SCSI drivers the Macintosh Plus can have loaded into memory at one time. A typical SCSI driver uses about 5K of memory. If you attached seven SCSI devices, you would use around 35K of memory for their drivers. This 35K or even 50K does not pose a problem. The real problem you have with the Macintosh Plus and SCSI devices is the electrical limitation. Four to five devices is probably the maximum that you can put on the SCSI bus due to the load placed on the SCSI bus by the SCSI devices.

Pascal III Editor: Inserting control characters

This article has been archived and is no longer updated by Apple.
The Pascal Editor recognizes 32 different control characters. The trick to producing them is to press the OPEN-APPLE key together with whatever key is required to obtain the desired control character, as described in the table on p. 136 of the Standard Drivers Manual. These characters go into the file with their high bit set to one, but that probably won't be a problem: most programs and peripherals ignore the high bit anyway.

LaserWriter IINTX: Printing HPGL Files from a PC

Can I write HPGL files from a PC to a Macintosh LaserWriter IINTX without converting them to PICT or PostScript?

This article has been archived and is no longer updated by Apple.
Briefly, the LaserWriter IINTX emulates an HP LaserJet Plus. LaserJets use PCL, not HPGL. A PC printing an HPGL print job cannot print to a LaserWriter IINTX.

Hewlett-Packard uses different printer control languages, including HPGL and PCL, for their different printers. HPGL is commonly used by CAD/CAM type programs for outputting to plotters. PCL is used by more common, generic programs for outputting to HP LaserJets and similar printers.

Apple's PostScript LaserWriters emulate Diablo 630s. Additionally, the LaserWriter IINTX emulates an HP LaserJet Plus; therefore, a program that uses PCL and is LaserJet-Plus-compatible can print to the LaserWriter IINTX when the LaserWriter IINTX is in its LaserJet Plus emulation mode. Again, you cannot print an HPGL print file directly (without file translation) on the LaserWriter IINTX.

If you want to print to an Apple LaserWriter, you must use a program that supports a Diablo 630, LaserJet Plus, or PostScript-compatible printer. If your program and drivers do not support these types of printers, you need to export and, possibly, translate the data before importing the data to a program that does--whether that program runs on a PC, Macintosh, or another system. Software that might help you includes PlotView and CADMOVER.

PlotView (formerly called MacHP) from Stevens Creek Software allows you to open and display Macintosh HPGL files on a Macintosh, and copy and paste them into other Macintosh programs for embellishment before printing to a LaserWriter. If you can use Apple File Exchange or a similar program and perform a generic text translation on the PC HPGL file, you can then open it with PlotView. This may work, but may require a little experimentation and manipulation with ResEdit or similar programs. Another option is to write your own AFE translator.

Another program that may work is called CADMOVER from Kandu, which a 2-D/3-D Macintosh-based vector graphics translation utility, with bidirectional IGES, DXF, PICT, MacDraw, Minicad+, MacConcept, HPGL, Minicad+, Dimensions, Hyperspace, and Space Edit.

We feel the easiest solution would have been to select a program on the PC that also prints to a PostScript printer or, at least, use a program that can save the file in a format (not just an HPGL print file) that can also be read by other Macintosh or PC programs that can print to a PostScript printer. There may be PC programs that open HPGL files and save in a more commonly used file format.

Internet Router: Local Net Setup Conflict

Regarding the AppleTalk Internet Router, what conditions cause the Local Net Setup Conflict statistic (shown in the Port Statistics window)? How do you locate and correct the problem?

This article has been archived and is no longer updated by Apple.
The AppleTalk Internet Router manual states:

"A Local Net Setup Conflict error is reported if another router on a network that is directly connected to this router lists a conflicting network number or range for that network."

This statement indicates that there is another router on the same physical cable as the AppleTalk Internet Router that is advertising a network number or range for that physical cable that is different from the network number or range in use by the AppleTalk Internet Router. The key to correcting the problem is to locate the routers that are attached to the physical cable with the problem and verify that they all are using the same network number or range for that physical cable.

A/UX: Troubleshooting Tape Backup Problems

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I haven't been able to back up much of anything. I tried to back up my X11R4 source disk (about 72MB), and "tar" keeps failing on the second tape. I tried:

tar clvbBf 16 72000 - | tcb > /dev/rmt/tc1

and tcb failed with an I/O error after about seven files were written to the second tape.

I tried:

tar clvBf 72000 - | tcb > /dev/rmt/tc1

and got the same error in the same place.

I also tried:

tar clvbBf 16 72000 /dev/rmt/tc1

This command backed up well into the second tape (but very slowly) and failed with a memory fault error.

The cmdo dialog for tar (using the tape cartridge) generates a command line:

tar clvbBf 16 4500 /dev/rmt/tc1

which writes only 4500 512-byte blocks to the tape.

Express Tape (a commercial backup product) fails on the third tape, when I try to back up the root partition.

I noticed the "time slice" parameter has dropped from 60 ticks to 5 ticks. If I run the "plaid" demo and a few more xdemos, things grind to a halt much more quickly than in version 1.1. (I have not yet received the A/UX driver that turns on the cache for the accelerator.)

Can you help?

This article has been archived and is no longer updated by Apple.
The first thing we noticed was a minor typo in each of the above command--they lack the input file(s) or directories. The first one, for example, should have an input file (/source-tree, for instance) specified in the command line:

tar clvbBf 16 72000 - /source-tree | tcb > /dev/rmt/tc1

We can't reproduce the problem. We used the command below to back up the entire root (/) directory onto two tape cartridges without any I/O error.

tar clvbBf 16 72000 - / | tcb > /dev/rmt/tc1

The problem with the "tar" command failing on the second tape cartridge may be bad spots on the second tape cartridge. Try replacing that tape cartridge with a new one.

The time slice parameter SLICE is set to 5 by default. However, the kconfig(1M) still states 60. This is an inconsistency. Try adjusting to a different value to fit your needs.

Published Date: Feb 18, 2012

A/UX 2.0: NBUF Values

I have an 8MB Macintosh. NBUF has a value of 337. The buffer size appears to have doubled since the last release--I was running with NBUF=1000 in A/UX 1.1. Should NBUF be increased? Do you have any tuning suggestions?

This article has been archived and is no longer updated by Apple.

In A/UX 2.0, the default NBUF value is 10% of the available memory after A/UX is booted, and the SBUFSIZE now is 2048 instead of 1024. The value of NBUF can be adjusted to fit your environmental needs via the "kconfig -n /unix" command. Increasing the number of buffers reduces the memory available for applications and may cause more paging.

Published Date: Feb 18, 2012

Macintosh: Key Caps desk accessory

This article has been archived and is no longer updated by Apple.

The Key Caps desk accessory is used to show the current keyboard mapping - that is, which keys correspond to which characters. It is especially useful for showing the characters accessed by the Option key, which are not typically displayed on the keyboard itself. The Key Caps menu, available when the DA is open, allows you to select and view any font available in your system. Key Caps can also be used to "type" characters into the Key Caps desk accessory using the mouse to click on letters. The characters can then be copied and pasted into another application if your keyboard is broken or inaccessible.

To print the Key Caps layout take a snapshot of the screen and print it. Search on "Screen Dump" for more information. It's not possible to screen dump the keys displayed on the Key Caps screen when the option key is pressed down. If you want a printout of the characters produced when pressing the option key, type them into an application, such as MacWrite or MacPaint, then print using the print dialog box.

To display all the characters in a given font, use ResEdit or the simple MS-BASIC program below.

```
10 c = 32
15 l = 0
20 Print CHR$(c);
25 c = c +1
30 l = l+1
35 If c > 255 Then End
40 If l < 50 Then 20
45 Print
50 Goto 15
```

This program prints the default (Geneva 12-point) key caps to the default screen. Add the following lines to your program to print other fonts and sizes contained on the BASIC disk:

```
5 CALL TEXTFONT (typeface)
--0 is system font, 2 is New York, etc.; refer to the Microsoft BASIC manual.

7 CALL TEXT SIZE (size)
--9, 12, 14 or whatever sizes are on the disk.
```

Printing: High-Volume Solutions from Printronix

My company does high-volume printing (about 50,000 pages a month). Do you have a solution fthat can handle this volume? The printer should be a 300 to 400 lpm printer. Can you help?

This article has been archived and is no longer updated by Apple.
We have seen Printronix P300-XQ and P600-XQ line printers working with Macintosh computers. This particular configuration used a serial-to-parallel converter to attach the Macintosh serial port to the parallel port of the Printronix. An ImageWriter driver with "Draft" selected was used as the printer driver. Again, this is not a support solution although it seems to work.

An alternative (although still unsupported) could include any mini/mainframe line printer that works with ASCII-based systems and a printer driver construction set, from DataPak Software, called Printer Interface II. Printer Interface II lets the user customize several aspects of the printer driver providing a method to send the correct printer control codes to the mini/mainframe line printer.

The Printronix P300-XQ does 300 to 400 lpm. The Printronix P600-XQ does 600 to 800 lpm. The lower numbers represent compressed printing; the higher numbers represent standard draft mode.

For more details, search the Technical Info library under "Printronix" and "DataPak Software"

Personal LaserWriter NT: Upgrading RAM to 8MB

The Personal LaserWriter NT literature states that you can upgrade the RAM in the printer to 8MB. How is this done?

This article has been archived and is no longer updated by Apple.

The Personal LaserWriter NT has two SIMM sockets that can accept either 1MB or 4MB SIMMs. Because both SIMMs must be of the same density, the total RAM can be either 2MB or 8MB. The Personal LaserWriter NT ships with two 1MB SIMMs. Therefore, the only upgrade path is to replace the two 1MB SIMMs with two 4MB SIMMs.

The requirements for the 4MB SIMMs are the same as for standard Macintosh II SIMMs, but they must be rated at 100ns or faster. They must also fit in a significantly smaller space than the Macintosh II family allows. This eliminates 4MB SIMMs made from lots of 1MB DRAM chips.

Here are several vendors that advertise compatible 4MB SIMMs:

The Chip Merchant
MacCenter
MacSystems/Lifetime Memory Products
Memory Plus
Stratum Technologies

To locate a vendor's address and phone numbers, use the vendor name as a search string.

A/UX: AppleShare, GatorBox and Oracle (8/94)

I have an existing LocalTalk-based network currently accessing an AppleShare File Server. I want to set up an Oracle database under A/UX and would like to be able to access the database from existing Macintoshes on LocalTalk. At the same time, I want to be able to access the A/UX system as an AppleShare file server.

I think I can use a GatorBox with GatorShare to set up the A/UX system as a server. Can the workstations talk to the Oracle database with this type of setup?

This article has been archived and is no longer updated by Apple.
You are correct that you need the GatorBox. However, GatorShare lets Macintoshes access an NFS server as if it were an AFP server. Oracle supports MacTCP connection via both LocalTalk and straight over Ethernet. The A/UX Macintosh does not have to be an NFS file server.

Also, you should be able to access the Oracle database and use the NFS server mounted on your desktop simultaneously.

The Macintosh running A/UX should have the full Oracle database software for A/UX. All other Macintoshes that need to access the server should be running MacTCP and the Network Station Oracle software. This Network Station software includes SQLNET for TCP and other utilities minus the database. In this case, your workstations communicate with the server via TCP/IP and SQLNET (not using AFP or NFS protocols), so you don't need GatorShare.

Canon Fax to Macintosh Connectivity Solution (11/94)

I'm trying to interface my Canon Laser Fax machines models L770 and L920 to a Macintosh II. The Canon machines feature RS-232 interfaces. Has anyone heard of Fax software for the Macintosh that lets these machines work with a Macintosh?

This article has been archived and is no longer updated by Apple.
We don't know of any Fax software that lets you interface a Macintosh with a Canon laser printer/Fax machine. Some manufacturers that design Fax machines license their interfaces to other Fax manufacturers. If the Canon laser printer/Fax machine was designed to interface to a computer, and if the interfacing logic is similar to an existing Fax machine, perhaps some existing software for another Fax machine might also work with the Canon laser printer/Fax.

Some third-party products support fax machines that use interfaces similar to the TE Fax (Relisys), AppleFax (Apple Computer), Flex Fax (Circuit Research), Orchid Modem (Orchid), and ProModem (Promethus Products). However, we don't know of any specific software available for the Macintosh that lets you interface to this product from Canon.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Macintosh-to-Siemens/Nixdorf Connectivity

I need to connect a Macintosh to a Siemens mainframe H60, running the PS2000 Operating System. I also need to connect a Macintosh to a Nixdorf M15-8870, running under UNIX.

Can you help?

This article has been archived and is no longer updated by Apple.
We contacted Siemens in the U.S., and they don't know of a solution for the Macintosh to connect to their H60 mainframe running BS2000 Operating System. In general, their H60 supports TCP/IP and RS-232, communication protocols and interfaces for terminals, modems, and IBM PCs connections. Because MacTCP and RS-232/422 are supported by Macintosh, you can make a simple connection between a Macintosh and the Siemens H60 mainframe. However, we don't have any specific connectivity solutions for a Macintosh and the H60 mainframe.

According to Nixdorf, there is no 8870 model running under UNIX, but their Targon/31/35 series does run UNIX. The 8870 models run under Nixdorf's proprietary operating system called NIROS. The 8870 models support multi-users, RS-232, CCITT V.24 interfaces, SDLC, BSC, asynchronous and synchronous protocols, and IBM 2780/3780/3740/3270 protocols.

Again, you can connect to the two machines, provided the underlying protocols and/or interfaces are supported by both machines (Macintoshes and third parties).

MacX & MacTCP: "unimplemented co-routine error 12" (11/94)

I am running a Macintosh Portable with MacTCP and MacX. When starting up MacX, I get the error message "unimplemented co-routine error 12." I get the same error message when I try to use NCSA Telnet without MacTCP. The same configuration worked on other Macintoshes.

Do you know of any problems using these two software components on a Macintosh Portable?

This article has been archived and is no longer updated by Apple.
The problem may be improper installation of CommToolbox, MacTCP, and/or MacX. We tested both MacX and NCSA Telnet 2.3 on a Macintosh Portable and didn't have any problem. Here are some things to check:

- Make sure that the CommToolbox is properly installed and that the "Communications Folder" folder was created in the "System Folder".

- Make sure that the "MacTCP" and "AdminTCP" CDEVs are in "System Folder" and that the "MacTCP Tool" comm tool is in the "Communications Folder" folder.

- Make sure that all MacX fonts are installed in the "MacX Fonts" folder.

- Make sure that MacTCP is properly configured on the network.

A/UX 2.0: "settc" and daiw" Commands

I cannot find two programs: "daiw" (the TROFF output formatter for the ImageWriter) and "settc" (set type and creator) commands under A/UX 2.0. I checked a "known good" master of A/UX 2.0, and I got this:

grep -i daiw /FILES
/mac/lib/cmdo/d/daiw Commando dialog source script for the daiw command
/usr/catman/u_man/man1/daiw.1.z formatted manual entry for daiw(1)

This indicates that there is a Commando dialog and a man page, but no executable daiw command. A "find" on the entire file system produced similar results.

Likewise, I searched for "settc":

grep -i settc /FILES
/usr/catman/u_man/man1/settc.1.z formatted manual entry for settc(1)

As you can see, there is a man page, but nothing else. Have these commands been removed from A/UX 2.0? Will they be replaced?

This article has been archived and is no longer updated by Apple.

```
We verified that neither the /usr/bin/daiw command (and its associated fonts
/usr/lib/font/deviw/*) nor the /mac/bin/settc program is present in the
released version of A/UX 2.0.  Manual pages for settc (1) and daiw(1) are
still available though.

The missing "settc" had been reported by others; "settc" has been replaced
by the "setfile" command in the /mac/bin directory in A/UX 2.0. However,
there is no manual page entry for "setfile".  According to A/UX Engineering,
the "setfile" command syntax is the same as MPW:

  setfile [options] file

options include:

  -a attributes   # attributes (lowercase = 0, uppercase = 1)
  -c creator      # file creator
  -d date         # creation date (mm/dd/yy [hh:mm[:ssIIAM|PM]])
  -l h,v          # ICON location (horizontal, vertical)
  -m date         # modification date (mm/dd/yy [hh:mm[:ssIIAM|PM]])
  -t type         # file type

Note: Period (.) represents the current date and time.

The following attributes may be used with the -a option:

   L   Locked
   V   Invisible
   B   Bundle
   S   System
   I   Inited
   D   Desktop
   M   Shared (can run multiple times)
   A   Always switch launch (if possible)
```

Personal LaserWriter NT: PageMaker 4.0 APD Workaround (8/95)

Where can I get the APD file that's needed by a Personal LaserWriter NT running PageMaker 4.0? (Evidently, the LaserWriter II version of APD works, but it displays spurious messages while you use it.)

This article has been archived and is no longer updated by Apple.
APD (Aldus Printer Definition) are files that Aldus provides primarily to their PageMaker customers. Apple does not supply Aldus Printer Definition files to PageMaker customers. Apple and third-party printer manufacturers do provide information to Aldus, so they can create their APD file for the specific printers.

Aldus Technical Support indicated that a Personal LaserWriter NT APD would be available sometime in the future. In the meantime, they provided a workaround for the only known issue when using the LaserWriter IINT APD with the Personal LaserWriter. A dialog box appears after the Print menu item has been selected. The dialog states:

Check printer type.

If you have trouble printing to
"{name of printer}" change "Printer:" from
"{current APD}" to "{printer type}"
in the Print dialog box.

For the described situation, it would read:

Check printer type.
If you have trouble printing to
"{name of printer}" change "Printer:" from
"LaserWriter IINT" to "LaserWriter
Personal NT" in the Print dialog box.

To eliminate this dialog box from the printing process, do these steps:

1) Copy the exact names in the "{current APD}" field and in the "{printer type}" field of the "Check printer type" dialog. In this case:

"{current APD}" = "LaserWriter IINT"
"{printer type}" = "LaserWriter Personal NT"

and Quit PageMaker.

2) Make a copy of the "LaserWriter IINT.apd" file.

3) Open the copy with a word processor or text editor.

4) Locate all occurrences of "LaserWriter IINT" and change to "LaserWriter Personal NT".

5) Save the copied and modified file in text format with the name "LaserWriter Personal NT.apd". Be sure the .apd extension is included.

6) Exit the word processor/text editor and restart the Macintosh.

7) Launch PageMaker, go to the Print dialog box, and select "LaserWriter Personal NT" from the "Printer:" popup menu.

AppleShare PC: 3COM EtherLink MC Card Problems

I have an IBM PS/2 model 55SX with 1MB RAM, 3COM EtherLink/MC card, MS-DOS 3.3, and AppleShare PC 2.01. The server is a Macintosh IIfx with HD80 SC and 4MB RAM with AppleShare 2.0, Internet Router 2.0, and a 3COM Ethernet card. The printer is a LaserWriter IINT. I can reach the printer. The PS/2 recognizes the server on the network, but can't mount it. For example, the F2 button is not enabled in the Chooser on the PS/2. The system asks me to run REDIR, but when I do, I get a Divide Error.

Here is the CONFIG.SYS file:

```
buffers=8
country=047, 865, c:\\dos\\country.sys
device=c:\\dos\\ANSI.sys
device=c:\\dos\\display.sys con:=(ega,865,1)

files=20
lastdrive=g
device=pro.sys 8 2 2
device=eth523.sys
device=buf.sys
device=idp.sys
device=spp.sys
device.lgl.sys
devise=epath.sys
```

This article has been archived and is no longer updated by Apple.
After unsuccessfully trying to duplicate the problem, I noticed what you entered for the CONFIG.SYS file. It looks like the 3COM installer was used at some time before trying AppleShare PC. All 3COM software must be inactive for AppleShare PC to operate. The 3COM software and the AppleShare PC drivers conflict with each other.

Remove the following lines from the CONFIG.SYS file:

```
device=pro.sys
device=eth523.sys
device=buf.sys
device=idp.sys
device=spp.sys
device=lgl.sys
device=epath.sys
```

It is also a good idea to remove any lines from the AUTOEXEC.BAT file that reference 3COM software. These lines will begin with runminds, msredir, or nb.

DAL: Teradata DB Support

I want to buy Teradata equipment, and I want an ad hoc query tool. Teradata offers something I haven't seen yet--EQT. Is there any relationship between that and the EQT for DAL (formerly CL/1)? Because we are interested in ClearAccess, when can we expect a DAL driver for the Teradata?

This article has been archived and is no longer updated by Apple.

We don't know of EQT from Teradata (now NCR/Teradata Corp.). From what we understand, the datamodels provided by Teradata database machines, like DBC/1012 models 2 and 3, are relational, and they are SQL-based. So it is possible to write a Data Access Language adapter for it.

As of release 1.3 DAL for MVS servers (TSO and VTAM) also support Teradata access.

EQT (Executive Query Tool) is a query tool developed by Red Brick Systems. It provides point-and-click access to relational databases, regardless of the workstation platform, the database server, or the server hardware. It runs on Macintosh and DOS Windows. Future releases will run on the OS/2 Presentation Manager, and UNIX workstations. It can retrieve data from Teradata, Oracle, Ingres, Sybase, DB2, Informix, and Rdb databases.

EQT for CL/1 is an old name for an announced product called Claris Query Tool, which uses three mechanisms to access databases: Data Access Language (DAL from Network Innovations), DB Library (Sybase), and SQL-Net (Oracle). The Claris Query Tool will be shipped in 1991. For more information about Claris Query Tool, please contact Dennis Ryan, Product Manager at Claris.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Folder Cannot Be Deleted: How to Fix

There is a folder that I cannot delete from an AppleShare server. I have rebuilt the desktop, reinstalled system software and AppleShare, and even started the server without AppleShare, so I could try to throw the folder away directly. Also, any file that is put into this folder disappears.

What is causing this to happen? Could it be bad sectors on the disk? How can it be most easily fixed?
This article has been archived and is no longer updated by Apple.
The most likely cause of the problem you describe is a corrupted directory structure. This type of problem could happen either on an AppleShare server or an individual Macintosh. Here is what we suggest:

1) Use Disk First Aid on the volume; this will sometimes repair slightly damaged directories.

2) Run "The Norton Utilities for the Macintosh", "Symantec Utilities for the Macintosh", or equivalent package to try to repair the volume. These utilities can repair damaged directories that Disk First Aid cannot.

3) Back up all the data on the hard disk and reformat it. This will solve the problem if all else fails.

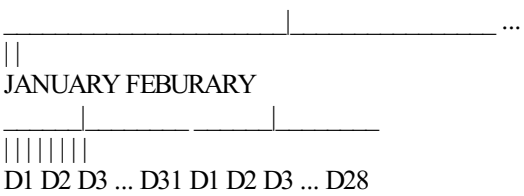
Pascal III: Listing large directories

This article has been archived and is no longer updated by Apple.
The Pascal III Filer reads the entire directory into memory before printing any of it, and so the number of files in a directory is limited. With a 128K Apple III, this limit is approximately 500 files; a ProFile with a directory containing more than 500 files, then, can cause problems.

SOS was designed to accomodate subdirectories so that large numbers of files can be stored and used with ease. A complex daily log of transactions, for instance, might be arranged like this:



This way, the pathname to the data for the last day of Feburary would be:

/PROFILE/TRANSCTIONS.82/FEBURARY/D28

By making use of SOS's ability to accomodate subdirectories, then, you can store far more than 500 files, as long as you never exceed the 500-file limit within any single directory.

Macintosh II: Connecting NTSC Devices to the Macintosh

I have a 25-Inch Sony Trinitron KX-2501A, a 40-Inch Mitsubishi VS-4003R and a Sony high-resolution projector, Model VPH722Q1.

I want to be able to use them for a presentation.

How can I tie these displays (RGB and/or composite) into a Macintosh II? Eventually, I want a capability for all three displays.

This article has been archived and is no longer updated by Apple.
We have been unable to track down any information on the Sony Trinitron KX-2501A. Generally, when a Sony product has the Trinitron title it is a consumer-level display unit. Extrapolated from that, it most likely provides NTSC input rather than RGB input.

The Sony VPH722Q1 is an NTSC composite projector. To provide the high-quality Macintosh images to which people are accustomed, a video projector that accepts RGB input at a horizontal scan rate of 22 MHz should be used. Generally, these projectors are known as having data projection capabilities. The Sony VPH722Q1 is not considered by Sony as a data projection unit.

The Mitsubishi VS-4003R accepts only NTSC input. Using the above assumption concerning the Sonys and the fact that the Mitsubishi is NTSC, the following information applies to connecting NTSC devices to the Macintosh.

The Macintosh standard video output is RGB. To display this video output on a NTSC device certain things need to take place:

- The typical scan rates for RGB are much higher than that of NTSC; this scan rate must be lowered to meet the NTSC RS-170-A specifications.

- RGB is a component video signal, NTSC is a composite video signal; the RGB signal must be converted to the composite signal.

- The RGB cable is a multi-conductor cable. The NTSC cable is a two-conductor cable. The device that does the RGB-to-NTSC conversion typically provides the correct output connector for NTSC, and sometimes provides a pass-through for RGB.

The scan rates are determined by the video card residing in the Macintosh. Therefore, the first item to address is the video card to be used. Some video cards are designed as RGB scan rates only. Some can be configured to the appropriate rate. Others can output NTSC scan rates only. If you have a video card that can be configured to the correct rate, the addition of the converter and cable is all that is required. If your current card is RGB only, then you need a new card.

Once a video card configurable to NTSC scan rates is present in the Macintosh, the next step is to locate a converter box that works with the particular video card in use. Sometimes this box is available only from the manufacturer of the video card, other times third parties provide a selection to choose from. This depends on the card.

When a converter box that works with the video card is located, the remaining step is to plug the NTSC output of the box into the NTSC input of the monitor. This is exactly like plugging a VCR into a television. Most often this is a RCA-type phono plug to RCA-type phono plug cable.

The other common connector is the BNC connector. Adapters are available to convert the connectors from one style to the other. The newer converter boxes appearing on the market also offer an S-Video connection. These connectors are

mini-4 connectors (similar to Apple's Mini-8 connectors). They are found on newer televisions, monitors, Hi-8mm/Super-VHS/EdBeta video cassette recorders, and camcorders. The S-Video connection yields a higher-quality image than the usual NTSC signal. S-Video, however, is still an NTSC signal.

There are image issues when sending the Macintosh screen to NTSC devices, due to the lower-quality image of the NTSC environment. The simplest rule is" "develop your presentation on an NTSC monitor". Most of the other issues fall into place if this rule is followed.

You can minimize other issues facing NTSC images with these tips:

- Use larger font sizes -- 24 points minimum.

- Use color palettes designed for the NTSC environment (MacroMind Director includes an NTSC palette).

- Use larger graphic images, small details disappear.

- Use two-pixel-wide horizontal lines to avoid flicker.

- Centering the information, outer edges disappear from display (known as NTSC safe area or TV safe area).

The Macintosh Display Card 4/8, 8/24, and 8/24 GC can be used with NTSC/S-Video devices by including either RasterOps' Video Expander Box or Truevision's VIDI/O Box. Both of these RGB-to-NTSC converters let the new Macintosh Display Cards' signal be sent to NTSC/S-Video televisions and video recorders. For additional information about the details of connecting the Macintosh Display Cards to NTSC, search under "Macintosh and NTSC".

LaserWriter IINTX: Serial Connection Parameters

I have a LaserWriter IINTX attached serially to a Novell Netware server and am trying to print PostScript files. But it's not working.

The LaserWriter is configured for PostScript, serial interface, and DSR/DTR handshaking. The port settings are 9600 baud, no parity, 7 data bits, 1 stop bit, and no XON/XOFF. The server settings match and the cable is a full handshake cable.

This article has been archived and is no longer updated by Apple.
Check the data bits setting; the default LaserWriter IINTX setting is for 8 data bits. Switching the server to 8 data bits, or the LaserWriter to 7 data bits should solve the problem. The new "LaserWriter IINT/NTX Owner's Guide" correctly states that 8 data bits is the default. Also, check the following to be sure all settings are correct.

It sounds like you have the server connected permanently to the serial port. We are assuming that the DIP switches are set for this configuration. The DIP switches should be set to:

Switch 1: Down
Switch 2: Down
Switch 3: Up
Switch 4: Up
Switch 5: Up
Switch 6: Down

This sets the LaserWriter IINTX RS-232 port to 9600 baud and the RS-422 port to 0 baud and sets the LaserWriter to PostScript batch mode and DSR/DTR handshaking. These will remain as the default settings for the LaserWriter until the switches are changed.

The other default settings that you cannot set with the DIP switches are no parity check, 8 data bits, and 1 stop bit. You change these parameters and those set with the DIP switches by using PostScript.

The PostScript code that you need to send to the LaserWriter IINTX to change these parameters is:

```
serverdict begin 0 exitserver
statusdict begin PORT BAUD OPTIONS setsccbatch
```

In place of PORT, you need to put the number of the port you want to change. Replace PORT with 9 for the RS-422 port and with 25 for the RS-232 port. The BAUD parameter is simply the data transfer rate you want to use.

The OPTIONS parameter is a little more difficult. You need to know what kind of parity you want to use, what kind of handshaking you want to use, how many data bits, and how many stop bits. Use Table C-1 on page 121 of the LaserWriter IINT/NTX Owner's manual (Table C-5 on page 153 of the new manual) to find the option numbers.

In your case, for the RS-232 port at 9600 baud with no parity, DSR/DTR handshaking, 7 data bits, and 1 stop bit, this is the PostScript program:

```
serverdict begin 0 exitserver
statusdict begin 25 9600 36 setsccbatch
```

Download this PostScript program to the LaserWriter IINTX to see if setting the data bits to 7 fixes the problem.

Lanier WP Systems: File Transfer to/from Macintosh

I am looking for a file transfer solution between the Macintosh and a stand-alone Lanier word processing system. Do you have any ideas?

This article has been archived and is no longer updated by Apple.
There are a couple of possible solutions. However, they are really good only for infrequent or one-shot transfers. If you want to consistently transfer the files, there isn't a really good solution like Apple File Exchange translators, because it is unlikely that the Lanier word processor uses a format for its disks that could be read by AFE. The other matter is the format of Lanier word processing files.

The first possibility for transferring the files from the Lanier would be to print the files out of a Lanier serial port directly into a terminal program like MacTerminal running on the Macintosh. This would require that the Lanier has a serial port and can print to that serial port. It would also require that you have the appropriate cable to connect the Macintosh to the Lanier. A drawback to this method is that you lose all of the formatting of the Lanier files.

The second possibility is to use a data conversion service. One that we know of that can work with Lanier and Macintosh formats is Pivar Computing Services. Search the Technical Info library under "Pivar" for details.

MultiFinder: Background Print Monitor Errors

Article Change History

1/20/93 - UPDATED
* Vendor information.
2/02/91 - REVIEWED
* For accuracy.

I have two problems that involve MultiFinder Background Printing. The problems show up on multiple Macintosh computers running Macintosh System Software Version 6.0.5 and LaserWriter Driver Version 6.0.

1) After printing a document, the Print Monitor window shows that the print job is "Processing". However, nothing happens (for several hours, if left alone). Only by going into the System Folder and double-clicking Print Monitor will the job finally be released.

2) When trying to print a document, a dialogue box comes up and says "Print Monitor found an internal problem, where=6; why=-37." Replacing Print Monitor and reinstalling the system did not correct this situation.

This article has been archived and is no longer updated by Apple.
These problems are probably related.

* "where=6" is a Print Monitor error: open working directory failed.

* "why=-37" is a System error: dNmErr, a bad name error.

We recommend the workarounds below; do them in the listed order. We advise printing after each step or every couple of steps to see when the problem is eliminated.

1) Throw away the Spool Folder (a new one will be created automatically next time you use Print Monitor).

2) Repair the volume with Disk First Aid.

3) Repair the volume with Norton Utilities from Peter Norton Computing, (acquired by Symantec Corp and/or SUM Tools from Symantec, or perhaps PC Tools/Macintosh from Central
Point Software. (For address and phone information, search the Tech Info Library under the company names.)

4) Check for and eliminate any viruses.

5) If none of the above works, backup any information you wish to save and then reformat the drive.

Using MacX under Macintosh OS With DECwindows on VAX (1/95)

To use DECwindows clients using MacX under the Macintosh OS, what files need to be on the VAX and what files need to be on the Macintosh?

This article has been archived and is no longer updated by Apple.
On the Macintosh side, for the MacX server to work properly, the Macintosh should be installed and configured with MacX, MacTCP, and CommToolbox. You should have the MacTCP tool in the Communication Folder within the System Folder. On the VAX site, if the DECwindows client is running under VMS, you need to get the "PATHWORKS for Macintosh" software from DEC, which includes some fonts and communications tools for both Macintosh OS and VAX/VMS. If the VAX is running under Ultrix or UNIX, no special files are needed, because TCP/IP transport is usually supported in UNIX OS.

Note: The READ ME file that comes with the MacX lists a few known problems/reasons/solutions for MacX and X11 client applications and troubleshooting tips.

A/UX: POP (Post Office Protocol) Information (9/94)

I want to use TCP/Connect II with smtp and A/UX. It needs software called POP. Do you have this software? What are its functions? Is it standard on other UNIX systems?

This article has been archived and is no longer updated by Apple.
There are three versions of POP (Post Office Protocol): POP, POP2, and POP3. The detailed specification of POP is described in RFC 918 (obsolete), RFC 937, RFC 1081, and RFC 1082.
Basically, the intent of the original Post Office Protocol (POP) was to let a user's workstation access mail from a mailbox server. It uses the Simple Mail Transfer Protocol (SMTP) to post mail from the workstation to the mailbox server. The POP protocol is dependent on TCP (Transmission Control Protocol). Below is the POP protocol:

The server is listening for a connection with the protocol. When a connection is opened, the server sends a greeting message and waits for commands. When commands are received, the server acts on them and responds with replies.

The client opens a connection, waits for the greeting, then sends the USER and then the PASS commands to establish authorization to access mailboxes. The client begins a mail reading transaction with either an RDEL (to read and delete all messages from a mailbox) or a RETR (to simply read all messages from a mailbox). The server opens and locks the mailbox and responds with the number of characters in the mailbox. Then, the client asks for the data to be sent by issuing the RCEV command. The server responds by sending the mail data.

When all the data has been received, the client sends the RCVD command. If the transaction started with the RDEL command, the server now deletes the mail data from the mailbox. In any case, the server closes and unlocks the mailbox. The client terminates the session with the QUIT command. POP2 is designed for an environment of workstations and servers on a low-delay, high-throughput, local networks (like Ethernets). The POP2 server is listening on TCP port 109.

POP3 lets a workstation dynamically access a maildrop on a server host. Usually, this means the POP3 is the means a workstation (client) uses to retrieve mail from the server. The POP3 server listens on TCP port 110.

Any UNIX system (like A/UX) that supports TCP can implement a POP server. There is public domain POP server software available from UC Berkeley at the following Internet address (via ftp "anonymous" and any password):

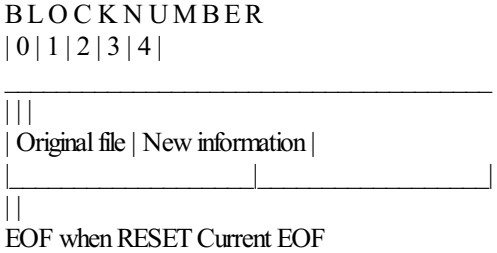
Pascal III: SEEK

This article has been archived and is no longer updated by Apple.
SEEK has a problem when used with an Apple II Pascal formatted diskette. When SEEKing a record that has been added to the file since the last RESET, it either takes a long time to find the record, or else Pascal stops with a System Failure error.

This commonly happens when you increase a file's size with PUTs and then use a SEEK to access one of the new records. Further operations on the file may destroy it.



For example: a SEEK to a record in the last half of block 2, block 3 or 4 causes undesirable results.

If you must extend a file, RESET the file before using SEEK.

AppleTalk for VMS 2.0.6: Fixes Error Message Issues

I get error messages (one every 10 secs.) generated on the VAX/VMS coming from AppleTalk. I am using AppleTalk for VMS 2.0 on one machine and AppleTalk for VMS 2.0.5 on another one. Is this allowed? The error messages are related to the exchange of RTMP packets. The errors are on the operator.log files or via the reply/enable command. This is the error message:

%ATK-W-INVPACREC, Invalid packet received
DECTECTED IN ROUTINE RTMPSktListener 1
This article has been archived and is no longer updated by Apple.
One of the major changes between AppleTalk for VMS 2.0 and 2.0.5 is that the definition of an invalid packet was changed to exclude a large number of packets that had previously been accepted as valid. This was done because a number of the packets that were previously being accepted were actually very badly-formed packets and were causing the bridge process to crash.

However, things were tightened up so much that packets that valid were rejected. Version 2.0.6 resolves this, and you should get it from the same source from which you got version 2.0.5.

Using version 2.0.6 may resolve your problems. It is also possible that there are bad RTMP packets being generated on the network. In this case, you will continue to receive the warning messages. The ATKBRIDGE.LOG file will contain the actual packets that are being rejected, and you can often identify the sender from the data in this log file.

Either way, you should be using the latest version (2.0.6) on both VAX systems. Version 2.0 has a large number of problems, so the machine running that version should be upgraded.

Finally, if at all possible, you should move everything to AppleTalk Phase 2 and PATHWORKS (formerly LanWORKS). That is the direction we are headed, and you should use AppleTalk for VMS 2.0.6 and 2.1 only as interim releases, until you are ready to install PATHWORKS.

Monitor Cables: Pinout Information

From time to time, I need pin-out details for various Apple monitor cables. Do you have a chart of this information?
This article has been archived and is no longer updated by Apple.
Here is the pin-out information for various Apple monitor cables. The Apple part number is molded into the connector housing of all Apple monitor cables. For additional information on signal descriptions see the "Guide To The Macintosh Family Hardware" available from APDA and Addison Wesley.

Cable Part #: 590-0161
Used On: Hi-Res Monochrome Monitor, Hi-Res RGB Monitor

DB-15	Description	DB-15
1	Red Video Gnd	1
2	Red Video	2

Mouse Compatibility: Macintosh Plus and Apple II Computers

My official Apple mouse works on my Macintosh Plus, but not on my Apple II computer. What does this mean?

This article has been archived and is no longer updated by Apple.

There are two vendors for the mouse that works with the Macintosh Plus and Apple II line. If you switch mice between systems, the mouse may not work.

One vendor's mouse works with both lines, and the other works only with the Macintosh Plus:

- The mouse identified as "Made in the US" works on both computers.

- The other is identified as "Made in Japan".

All service stock is of the compatible version (P/N 661-0400).

IINTX w/Rev 3 ROMs: Format HD w/LW Font Utility 2.0.2

I recently upgraded my LaserWriter IINTX logic board with revision 3 ROMs. The third-party fonts cause initialization errors when printing. However, if I move the same external hard disk to a non-upgraded LaserWriter IINTX, these fonts print just fine. Where's the problem?

This article has been archived and is no longer updated by Apple.
The LaserWriter IINTX with Rev 3 ROMs does not work properly with a hard disk formatted with the LaserWriter Font Utility 1.x. You need to reformat the disk and copy the fonts back onto the hard disk using the LaserWriter Font Utility 2.0.2. There is no way to make this procedure easier.

Macintosh Portable: TCP/Connect & NCSA Telnet Compatibility

I recently read that versions of NCSA Telnet, including NCSA Telnet 2.3 and the current version of TCP/Connect, do not work with the Macintosh Portable.

Is this a MacTCP (driver) problem or is it purely application-based? Should TCP/Connect II offer a solution?

This article has been archived and is no longer updated by Apple.
The incompatibility is with the applications, not with MacTCP. InterCon told us that the latest version of TCP/Connect (version 1.0.1) does work properly with the Macintosh Portable. As of November, NCSA was preparing version 2.4 of NCSA Telnet. Version 2.4 will work with the Macintosh Portable. For more information, please contact: NCSA and InterCon Corp. Both are listed in the Technical Info library.

Macintosh SE 2/40 Upgrade: SIMM Requirements

To upgrade a Macintosh SE 2/40, do the two additional 1MB SIMMs need to be the same speed as the original 2MB SIMMs?

If so, is there any way to determine the speed of the installed RAM without opening the Macintosh SE case?

This article has been archived and is no longer updated by Apple.
The Macintosh SE 2/40 requires SIMMs that are 150ns or faster. If the SIMMs already in the Macintosh SE are 120ns, you can add two more that are 150ns. The important thing is that the SIMMs in each group (group A is SIMM slot 1 and 2; group B is SIMM slot 3 and 4) must be the same speed.

The only way to tell the speed of the RAM installed is to look at the RAM chips themselves. Typically the 120ns RAM chips will have a "12" printed on them and the 150ns RAM chips will have a "15".

Pascal III: Accessing the extra memory (1 of 5)

This article has been archived and is no longer updated by Apple.
Apple III Pascal is upwardly compatible from Apple II Pascal. One of the constraints this imposed on the design of Pascal III was the restriction of the data space to 64K bytes. This restriction has been made clear on all specifications of the product. However, since the system uses additional space for SOS, drivers, graphics, the interpreter and code segments, this restriction may still interfere with programs that use large quantities of data.

To illustrate the steps involved in accessing more data, below are some small assembly routines. They ask SOS to allocate more space for the program, allow transfers of data back and forth to that space, then deallocate the space. On top of that is built a simple string package which stores up to 128K of string values in this space. Though the memory within this space may be managed only in the simplest of ways, the space can still be very useful.

The routines consists of three portions:

A. An assembly language routine containing macros that the SOS interface needs.

B. A fancy version of MOVELEFT that moves bytes from one location in banked memory to another. It understands the memory addressing of the Apple III, and so it increments pages accordingly.

C. A Pascal unit that uses the first two programs to implement the string routines.

Serial NuBus Card: Pinout Information

This article contains the pinouts for the Serial NuBus (NB) Card.
This article has been archived and is no longer updated by Apple.
Here are Apple Serial NB Card D-62 Connector Pinouts. There are two types of cables, the Hydra cable with four RS-232-C connectors, and the V.35 cable with one RS-232-C connector and one V.35 connector.

The term "RS-232" as used here refers to a signal that is single-ended and driven between +/-12V.

The terms "RS-422" and "X.21" as used here refer to a signal that is differential and driven +/-, measured differentially.

Pin #	Signal	Function
1	+CA1F	X.21 Control, +CHA1, OUTPUT
3	-CA1F	X.21 Control, -CHA1, OUTPUT
6	+CB1F	X.21 Control, +CHB1, OUTPUT
8	-CB1F	X.21 Control, -CHB1, OUTPUT
16	+IA1	X.21 INDICATION, +CHA1, INPUT
44	1DCDA/-IA1	RS-232 Data Carrier Detect/X.21 INDICATION, -CHA1, INPUT
11	+IB1	X.21 INDICATION, +CHB1, INPUT

Serial NB Card: Custom versus Extender Cable

I am using MacX25 and a Serial NB card. The synchronous modem is located in a different room from the Macintosh, about 10 meters away. Is it possible to get a connecting cable? What is the maximum length we can reach with RS-232 cable between Macintosh and modem?

If this cable does not exist yet, we need specifications to build such cable with a J-62 on one side and one RS-232-C on the other.

This article has been archived and is no longer updated by Apple.
We recommend contacting a cable distributor like Black Box and ordering one of their straight-through extender cables. This is far less expensive than having a custom "62-25"-pin cable built. It is also a faster solution, as this cable is fairly common and available in a variety of lengths. Request a cable with all pins attached, with one plug and one socket. You might want to describe the cable length (10 meters plus 3 feet, the length of the "Hydra" cable, which is within RS-232-C specification of 50 feet), and the data rates you intend to use.

Macintosh Communications Toolbox: Wyse Terminal Emulation

I'm looking for a supplier of terminal emulation software that will do the Wyse 50 type terminal. Our N&C Product manager tells me that the Wyse is a superset of the VT102 emulation, but I don't think the VT102 has enough functionality.

I'm thinking about the Macintosh Communications Toolbox as a route to supply this requirement. Can I get the technical details required to assess how difficult it will be to provide the appropriate communications tools to emulate the Wyse?

This article has been archived and is no longer updated by Apple.
Mainstay hasn't distributed their Telescape terminal emulation software for awhile. So, unless you already have a copy and want to invest development effort into a discontinued product, this probably isn't the development environment for you. We don't know of any other third parties that offer a Wyse terminal emulator, even one where you have to write a script like with Telescape.

However, the Macintosh Communications Toolbox may be the ideal development tool for you. There is a Macintosh Communications Toolbox folder on the Apple Developer Web page on the internet at:

http://devworld.apple.com

Here you'll find general Macintosh Communications Toolbox information. This includes product information, common questions and answers relating to the Communications Toolbox, tools and sample code, listings of third-party products that support the Communications Toolbox, and ongoing discussions on the Comm Toolbox. More technical details are found in the "Macintosh Communications Toolbox," and the "Communications Tools, Basic Connectivity Set" packages from APDA.

A more straightforward solution is to use another terminal emulator, if possible; many hosts will support VT100, VT52 or other terminals. Perhaps emulating another terminal will give you the capabilities you require.

A/UX and SGML (Standard Generalized Makeup Language)

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

Is there a version of SGML (Standard Generalized Makeup Language) for A/UX 2.0?

This article has been archived and is no longer updated by Apple.
We don't know if SGML runs under A/UX. However, SoftQuad, Inc. does have some software products related to SGML for the Macintosh OS. Their products include:

- SoftQuad RulesBuilder is an Interactive editor for creating SGML DTDs (Document Type Definitions), which, when compiled, also acts as a SoftQuad Author/Editor rules files.

- SoftQuad Author/Editor CALS is a text entry system that provides easy access to the power of structured editing based on SGML, the U.S Government's publishing standard for the Computer-Aided Acquisition and Logistics Support Initiative (CALS).

- SoftQuad Author/Editor is a context-sensitive text entry system that meets the requirements of the Standard Generalized Markup Language (SGML).

For more details, search the Technical Info library under "SoftQuad."

TA44952_Apple_IIGS_DOS_and_Hard_Drives_(TIL06397).pdf

Apple IIGS: DOS 3.3 and Hard Drives

Is it possible to partition the hard drive of a Apple IIGS, so one partition contains DOS 3.3 and applications and the other contains GS/OS? I tried it, and now the IIGS can't recognize DOS 3.3 floppy disks.

This article has been archived and is no longer updated by Apple.
DOS 3.3 was created when hard disk drives were only a dream for microcomputers. Thus, DOS 3.3 and previous versions understand only the 140K 5.25-inch disks. DOS 3.3 does not understand the 3.5-inch disk and hard-disk environments. When hard disks did appear for the Apple II family and DOS 3.3 was still the operating system of choice, individual hard-drive manufacturers devised independent schemes for dividing their products into multiple 140K volumes so DOS 3.3 could work with the hard drives. ProDOS was created to overcome the limits that DOS 3.3 imposed on storage volumes.

GS/OS would require a File System Translator (FST) to recognize the 5.25-inch disks of the DOS 3.3 operating system. However, the FST would be of no assistance in providing DOS 3.3 partitions on a hard disk, because the lack of hard-disk support is a limitation of DOS 3.3 itself, not the FST.
To use DOS 3.3 applications on an Apple IIGS requires restarting from a 5.25-inch DOS 3.3 disk.

A/UX: Moniterm Monitor Compatibility Issue

My group just received ten copies of A/UX 2.0 and ten Macintosh IIci systems. We are using Moniterm 21-inch color monitors. The Macintosh OS boots fine. When the system switches to A/UX, the monitor goes blank during the boot process. Is this a known Moniterm problem? Is there a workaround? Tech support at Moniterm didn't have a clue what A/UX was and had never heard of a problem.
This article has been archived and is no longer updated by Apple.
Typically, third-party video cards have had incompatibilities with A/UX. This goes back to A/UX 1.0. The manufacturers of the cards have had to release new ROMs to get their video cards (and therefore displays) to function properly with A/UX. SuperMac, RasterOps, and other manufacturers have done this.

Because there is no software workaround possibility, the burden of compatibility with the A/UX video drivers rests with the hardware manufacturer.

We will contact Moniterm's tech support and bring the issue up with them again. We suggest that the customer do the same if they want to use these monitors with A/UX 2.0. There may not be too much hope of a solution, if they are not even aware of A/UX. Furthermore, it would be unlikely that there would be a quick solution since ROM upgrades typically take a while.

The other route would be to try similar video cards and monitors from a third-party company that supports A/UX, and this may be the only solution depending on Moniterm's response.

Applesoft: Understanding FRE(0)

This article discusses the PRING FRE(0) command.
This article has been archived and is no longer updated by Apple.
PRINT FRE(0) displays the amount of memory available for Applesoft varibles.This value may be negative due to the way Applesoft handles integer numbers on 48K systems. Numbers greater than 32767 appear to have 65536 subtracted from them; in such a case, add 65536 to the value returned in order to get the number of free bytes.

For example:
1000 PRINT FRE (0) - 65536 * (FRE (0) < 0)

PRINT FRE(0) can cause the Apple to hang when it's executed in command mode immediately after loading your program from a diskette or using Applesoft RENUMBER. This hang is due to the variable pointers not resetting properly. Type CLEAR before entering PRINT FRE(0) to return the expected results.

The following program checks the memory for string variables; however, it doesn't give the expected results.

```
10 DIM A$(100)
20 B$ = "ABC"
30 FOR I = 1 TO 100
40 A$(I) = B$
50 PRINT FRE (0) + 65536
60 NEXT I
```

Since B$ is assigned to a string constant in line 20, and the pointer for A$(I) is assigned B$ (line 40), the PRINT statement in line 50 prints the same number. If we change line 40 to read:

```
40 A$(I) = B$ + "D"
```

the program uses memory for each assignment, because concatenation creates a new string in the free memory space each time the new line 40 is executed.

Using British Keyboard on U.S. Macintosh

Can I use my British keyboard with an American Macintosh?

This article has been archived and is no longer updated by Apple.
There are a couple of ways to use the Apple Desktop Bus British keyboard with a United States system. Both involve modifying the System Software running on the Macintosh.

The first method is to install the British System software on the Macintosh. This makes all of the necessary resources available, so you can use the machine exactly as you would in the UK.

The second method is to take the necessary resources from a British System Tools disk and install them in the System file on the Macintosh in question. If all you want is to map your keyboard properly, then you need the British 'KCHR' resource. You can use ResEdit to transfer a copy of this resource from the British System to the System file on the Macintosh. Once you've done this, choose the British keyboard mapping through the use of the Keyboard CDEV in the Control Panel.

If you want British sorting as well as British numerical and date formats, then you must copy all the British "itlX" resources too, where the "X" includes b,k,1,2,3,4. At this point, you would probably do better installing the British software, because the international software typically includes keyboard mapping for US keyboards, too.

Either way, the keyboard will function properly with a Macintosh manufactured in the United States.

HyperCard 2.0: Earlier XCMDs and XFCNs Compatibility

Is there a list of XCMDs and XFCNs that are known to work with HyperCard 2.0? I am converting a mission-critical application from HyperCard 1.2.5 to HyperCard 2.0. The application uses a lot of WindowIt XCMDs and MitemView.

This article has been archived and is no longer updated by Apple.

As of October, 1990, there was no published list of external routines compatible with HyperCard 2.0. Because the list of available routines changes every day, we doubt that there will ever be such a list. Testing results have shown that better than 80 percent of the tested externals work fine with HyperCard 2.0. We know this is not the answer you're looking for, but it's all we have.

For information on specific XCMDs and XFCNs, we suggest you contact the developer directly.

WindowIt, originally from Third Wave Computing and then Heizer Software has been returned to the original developer. As far as we know, it will not be modified to support HyperCard 2.0.

DAL: Shared Access to Rdb Database

I am having a problem with shared access to an Rdb database under DAL. Here are commands from the VMS $ prompt and their results:

```
$ icl1
Network Innovations Interactive CL/1 Demo
Execution begins...
CL/1 version 1.11
Execution Completed Successfully

begin> OPEN RDB DBMS ;
more> USE LOCATION "CL1$SYSTEM" ;
more> OPEN RDB DATABASE "CL1DEMO" FOR SHARED READONLY ;
more> GO
begin> SELECT * FROM OFFICES; PRINTALL ;
more> GO
.
.
.
data from above database displayed
.
.
.
```

Meanwhile, from another process (once the above user has attached to the database and started a transaction), the following command:

```
$ RMU/DUMP/USERS CL1$SYSTEM:CL1DEMO
```

shows that the above DAL commands produced a read/write transaction on the RDB database. From all the tests I have done, no read-only transaction is possible on an Rdb database using DAL.
This article has been archived and is no longer updated by Apple.
The symptom you described is one of the restrictions and limitations with DAL and Rdb. Basically, DAL provides protection using a model based on databases and tables, while Rdb uses a model based on protection. We checked with Network Innovations, and they have provided the DAL 1.2 Technical Notes, in which item #10 describes the restrictions and limitations with DAL and Rdb. The following is the text for that note.

DAL Technical Note # 010
Data Access Language (DAL) and Rdb

This tech note discusses restrictions and limitations with DAL and Rdb.

The Rdb DBMS adapter for the DAL Server is best viewed as a VAX/VMS C application which uses Rdb's Dynamic SQL interface to access Rdb databases. Accordingly, any DAL user who intends to access Rdb databases should ensure that his or her account is set up with the proper VMS privileges and quotas required by Rdb. DAL users should also note that any current restrictions or problems in Digital's Rdb and Dynamic SQL will also affect the DAL Rdb DBMS adapter.

For example, when Rdb performs arithmetic operations on floating point data types such as the SQL aggregate function AVG(), Rdb rounds any decimal result to a whole number. Consequently, DAL client queries containing aggregate functions on decimal or float datatypes will return rounded numbers when executed in Rdb.

Listed below are some specific Rdb related problems and their workarounds or explanations:

- Problem #1: Referring to multiple databases by dbaliasname (AuthID)

To support multiple Rdb databases, the DAL Server Rdb Database Adapter uses the DECLARE SCHEMA statement in Rdb's Dynamic SQL for each database opened. In Rdb, each database or schema is referenced by an "authorization identifier" or AuthID. DAL uses the dbaliasname specified in an OPEN DATABASE statement as the AuthID. (Or when a dbaliasname is not specified, the database name is used as the alias and AuthID by default). For example:

dbaliasname AuthID

- open database "sample"; sample sample
- open database "reservations" alias "test"; test test

Normally, the DAL Server keeps track of the AuthID for you. However, if you mix normal DAL statements with Rdb statements (via the DAL EXECUTE IMMEDIATE statement), you may need to use the AuthID when referring to tables, views, and indexes or when using the Rdb SET TRANSACTION statement. When referring to tables by the dbaliasname in DAL, the correct syntax is:

dbaliasname!table_name sample!offices

Rdb uses a period "." instead of an exclamation point "!" when referencing a table by the schema's AuthID:

AuthID.table_name sample.offices

(Note: DAL uses the period "." to prepend an owner name to a table. For example, sample!mark.offices in DAL indicates the table offices owned by mark in the database whose dbaliasname is sample.)

So, when using DAL's EXECUTE IMMEDIATE statement to set a transaction mode for a database or to reference a table, be sure to use the database's dbaliasname as the AuthID. For example:

```
open rdb dbms;
open rdb database "daldemo" alias test in location "msad$system";
execute immediate "create table small (text char(20))";
commit;
insert into test!small values ("xyz");
execute immediate "update small set text = 'small fails' where text = 'xyz' ";
rollback;
insert into test!small values ("xyz");
execute immediate "update test.small set text = 'test.small works' where text =
'xyz' ";
commit;
```

- Problem #2: Table Locking with DAL and Rdb

DAL provides a model for specifying the type of "protection" or "locking" desired when using a database or specific table. Both the OPEN DATABASE and OPEN TABLE statements allow for update modes (READONLY/UPDATE) and sharing modes (SHARED/PROTECTED/EXCLUSIVE). The default mode is UPDATE and PROTECTED. Typically this would mean that the user has a "READ/WRITE" lock on the particular table or database. The sharing and update modes are advisory and are passed on to the DBMS only WHEN APPROPRIATE.

Rdb provides a some what different model for specifying protections that does not map well with the DAL model. Rdb uses an extension to SQL transactions - the SET TRANSACTION statement - to signal the type of locking mechanism desired for that transaction. SET TRANSACTION modes are not persistent across subsequent transactions; they must be specified at the beginning of each new transaction or the default mode of "READ WRITE" and "SHARED" will be used.

DAL update and shared modes are not transaction based; that is, in the DAL model, update and shared modes are "global" session modes and are independent of beginning and committing sessions. Consequently, when a DAL user opens a Rdb database or table, specifying a particular update or shared mode, the Rdb transaction modes are NOT changed. The DAL Server does not alter the Rdb transaction modes because they CANNOT be changed in the middle of a Rdb transaction. One would have to commit the current transaction and begin a new transaction, setting the transaction modes as desired.

There are two possible problems:

1) PROBLEM: Lock Conflicts caused inserts and updates while using the Rdb default transaction modes.

SOLUTION: Commit as early and often as possible. Generic DAL applications should commit often to free any locks against tables and indexes accessed. Otherwise, other users might be locked out of one or more tables.

2) PROBLEM: User wants to specify READ ONLY to prevent locking.

SOLUTION: Applications tailored to Rdb can explicitly begin new transactions with the desired locking and update modes by using the Rdb SET TRANSACTION statement via the DAL EXECUTE IMMEDIATE statement. Below are examples:

```
open rdb dbms;
open rdb database "daldemo";
execute immediate "SET TRANSACTION READ ONLY;" in Rdb;
...queries....
commit; /* ends this transaction with READ ONLY */
insert into ....
```

commit;

- Problem #3: Attempting to query directly against the Rdb System Relations occasionally fails. For example, the following query fails:

SELECT RDB$RELATION_NAME FROM RDB$RELATIONS;

Explanation: When DAL is asked to do a query, it checks the syntax and content of the query statement to ensure that the columns and tables asked for exist in the database and to determine the data types of the results. Certain system relations contain columns with a "SEGMENTED STRING" data type (seg_str). This data type is not supported in SQL interface for Rdb 3.xxx (but will be supported in Rdb 4.0). Even though the column queried is not of the type seg_str, DAL looks at the entire structure (column names, data types, and lengths) to check for correct syntax and content. And in doing so, Rdb generates the following error code when it encounters a column with a seg_str: SQL-F-INVSSCONV, Invalid conversion for segmented string column RDB$VIEW_BLR.

WORKAROUND: Use the execute statement to create a view that specifies the non-seg_str columns desired. Then use DAL to query the view. This way, the DAL server's table look-up won't stumble on columns with the data type seg_str. The following example does this:

```
Execute immediate "create view temp as
select rdb$relation_name from rdb$relations";
commit ; /* don't forget to commit */
Select rdb$relation_name from temp;
```

Macintosh: Connecting to LAN-Based SQL Servers

I am implementing LAN-based SQL servers and would like to connect a Macintosh into that environment. I am looking at three products to run on an OS2/LAN Manager machine: Sybase, SQL Server, and Gupta. What can you tell me about connecting a Macintosh into these products?

This article has been archived and is no longer updated by Apple.

Sybase confirmed that a Macintosh can access SQL Server, if you have the DB Library and HyperDB Library for the Macintosh. These libraries are extra and not part of the basic SQL Server product. Connections are TCP/IP over Ethernet.

SQL Server is the name of the Database Server by Microsoft-Sybase. The Server runs on OS/2, and uses Named Pipes as the network protocol. Named Pipes is a network extension to OS/2--Microsoft's answer for interprocess communications on DOS or OS/2 PC LANs.

Gupta Technologies' SQL Base servers run on either DOS or OS/2, and uses NetBIOS as the network protocol. Gupta told us that there is no way to connect a Macintosh to SQL BASE.

Router Security Features

My company is having problems with our Ethernet backbone. Everyone is on the Ethernet, but one division controls all access to the net.

People from different divisions can see into the corporate office's zone and services. They can also print on corporate's LaserWriters. The corporate office wants to block transmission into their area but let everyone in the corporate office see services outside of their area. The corporate office needs access to the IBM hosts and VAX systems which are all on the backbone but in different divisions. Thus, total isolation is out of the question.

Right now, we connect our local divisions together with VitaLink boxes and T1 lines. I thought the VitaLink could do some of the above. But, even if they could, the one division controls them. The best solution for corporate is to find a router/bridge that has the above blocking/filtering features. If this is not possible, is there a device that at least allows controlled access to LaserWriters?

This article has been archived and is no longer updated by Apple.
There are several options available to allow zone and device hiding, but most of these products are LocalTalk to Ethernet routers like the Shiva FastPath or the Cayman GatorBox. There is one product that may provide the type of security you require; the NRC Macintosh-based Multigate router provides Ethernet-to-Ethernet routing and provides the ability to define parts of your network as insecure.

See the explanation below for a complete description of the options available for each device. Here is a summary of AppleTalk router security features:

LOCALTALK TO ETHERNET ROUTERS

Cayman Systems GatorBox

Zone Filtering:
Zone filtering prevents users in the filtered zone from seeing other zones on the network to which they are connected. This also prevents users in zones outside of the filtered zone from seeing devices in the filtered zone.

Laser Filtering:
Laser filtering is, in a sense, a subset of zone filtering. Where the zone filtering shields all of the devices from the outside, laser filtering lets you hide just the LaserWriters from anyone outside of its AppleTalk zone. This also prevents users in the filtered zone from seeing LaserWriters in other zones.

Tilde Filtering:
Tilde filtering lets you hide any device with a tilde character at the end of its name, so that it cannot be seen by anyone outside of its zone.

Shiva FastPath

Stay in Zone:
The stay-in-zone option prevents users in the filtered zone from seeing other zones on the network to which they are connected. This also prevents users in zones outside of the filtered zone from seeing devices in the filtered zone.

LaserWriter Security:
LaserWriter security is, in a sense, a subset of zone filtering. Where the zone filtering shields all of the devices from the outside, laser filtering lets you hide just the LaserWriters from anyone outside of its AppleTalk zone. This

also prevents users in the filtered zone from seeing LaserWriters in other zones.

Tilde Security:
Tilde filtering lets you hide any device with a tilde character at the end of its name, so that it cannot be seen by anyone outside of its zone.

NRC 2000

Insecure:
The insecure option lets you define sections of your Internet as "insecure." An insecure network's routing information is not propagated to any other section of the network, thus providing a way to control who can access the secure sections of the Internet.

APT

APT has announced an update to their AppleTalk routers. They now support device security across zones. Users can, for example, hide their LaserWriter from anyone not in their zone. You can also hide other devices, like file servers and NetModems.

The user can let other users on different zones and create different sets of access to different devices. For example, Zone A may have no access to your LaserWriter, but still have access to a File Server, while Zone B has access to all LaserWriters, but not AppleTalk ImageWriters or NetModems.

APT routers connect multiple LocalTalk, Ethernet, WAN, and Serial networks together, and supports Phase II AppleTalk. DDP/IP encapsulation is in the works.

ETHERNET TO ETHERNET ROUTERS

NRC Multigate Macintosh

Insecure:
The insecure option lets you define sections of your Internet as "insecure." An insecure network's routing information is not propagated to any other section of the network, thus providing a way to control who can access the secure sections of the Internet.

Cisco (CGS/MB/AGS)

The cisco router offers the ability to set up access lists that permit controlled access to your network. Access lists are set up to filter all in-bound network traffic from any network listed in the access list. Only traffic from networks not listed in the access lists is permitted into your network. Traffic from your network is still propagated to all other segments of your Internet.

LaserWriter: Source of Multi-bin Sheet Feeders

Is there a multiple-bin paper tray (holds 8 1/2 x 11, 8 1/2 x 14, and envelopes) for the LaserWriter IINTX?

This article has been archived and is no longer updated by Apple.
BDT Products, Inc. makes a multibin sheet feeder for the LaserWriter IINT/NTX. It's called LaserFeeder. They have two models.

- The Model 880 LaserFeeder has two paper bins and an envelope bin.
- The Model 890 LaserFeeder has three paper bins and an envelope bin.

The paper bins adjust to anywhere between 7.5 inches and 14 inches. Each bin holds 220 sheets. For more details, search the Technical Info library under "BDT Products."

HyperCard 2.0 Tour: "forward" Handler Bug and Workaround

I cannot navigate through the whole HyperCard 2.0 Tour stack. When I get to card 56 of the tour, I cannot use the button for card movement forward. All other buttons function properly. The same thing happens if you are on card 58 and try to go back a card to the previous card.

This article has been archived and is no longer updated by Apple.
Clicking on the "Next" button or pressing the right-arrow key on card 56 calls a handler named "forward". "Forward" calls a SysEnvirons XFCN and bases its choice of which card to go to on the value returned.

The XFCN is aware of all released Apple keyboards. However, the only options for the version of the stack we have are "Macintosh Plus Keyboard", "Standard ADB Keyboard" (includes the Apple IIGS Keyboard), and "Apple Extended Keyboard" (includes both domestic versions). You will encounter problems if you use any keyboard not listed above.

We don't know whether the tour stack will be localized to correct this problem. As a workaround, you can replace the existing "forward" handler with the one below.

```
on forward
hide message box
put SysEnv() into mySys

visual effect wipe left
if item 6 of mySys = "Macintosh Plus Keyboard"
or item 6 of mySys = "Standard ADB Keyboard"
or item 6 of mySys = "Apple Extended Keyboard"
then
go card item 6 of mySys
else
go card "Apple Extended Keyboard"
end if
end forward
```

Before modifying the script, you must set userLevel to 5 to do scripting.

Macintosh SE/30 Versus Macintosh IIfx: Video Speed

I have written code in Lightspeed C that makes many QuickDraw calls. When I run it on my Macintosh SE/30 with an external 19-inch mono monitor attached to a video card in the PDS, I notice that it runs significantly faster then when I run the same program on my Macintosh IIfx with either the Apple 4*8 card and the Apple 21-inch mono or an emachines 19-inch monitor also in black and white mode.

Is this because the PDS slot is faster than the NuBus slots or are there other factors? It seems that the 40 MHz Macintosh IIfx should be faster than the 16MHz Macintosh SE/30.

This article has been archived and is no longer updated by Apple.
Your assumption is correct. The Macintosh SE/30 PDS (processor direct slot) runs at 16MHz, while NuBus slots are limited to 10MHz. The increased bandwidth available to the PDS due to the 60 percent greater clock lets much more data pass than is possible with NuBus. NuBus overhead and arbitration widens this speed difference.

While the Macintosh IIfx itself runs much faster than the Macintosh SE/30, it cannot move data to the video RAM as quickly, because of this bus limitation. Programs which are calculation-intensive run much faster on the Macintosh IIfx, whereas programs that perform high-speed graphical operations can display faster on the Macintosh SE/30. The deciding factor is a matter of how many bits are being pushed across the bus to video RAM.

The current Macintosh II family shares the 10MHz NuBus speed. To alleviate this shortcoming caused by NuBus compatibility requirements, the Macintosh IIfx has its own PDS that is even faster than the Macintosh SE/30 PDS. It runs at the full speed of the Macintosh IIfx I/O bus, which is 20MHz, and is, therefore, capable of twice the bandwidth of NuBus, and 25 percent more than the Macintosh SE/30 PDS.

Unfortunately, we do not yet know of any compatible video cards. Although the Macintosh IIfx PDS looks similar to the Macintosh SE/30 PDS, the two slots are not at all compatible. We do not know of any cards in development and wouldn't think that this would be in any company's priorities. Macintosh graphics acceleration is tending toward specialized, dedicated graphics processors, like our 8/24GC card, that are NuBus cards and compatible across the Macintosh II family.

If you require faster video than the Macintosh IIfx can provide, your best alternative is to evaluate graphics accelerator cards. Two sources for such cards are Radius and SuperMac Technology. The Apple 8*24GC card is another option.

Connecting to ABANET via Telenet

I need to connect to ABANET. According to the information I received from ABANET they can be reached through Telenet. How can I reach ABANET via Telenet. I have a connection to the Belgian DCS network (Packet network, X.25).

This article has been archived and is no longer updated by Apple.

It sounds like ABANET has subscribed with Telenet, a X.25 Public Data Network provider, to get access to the X.25 PDN via Telenet. As a subscriber on a PDN, ABANET would have been given a unique address, not unlike your telephone number, that could be broken down into the world zone, country zone, a network digit and network terminal number.

Therefore, to reach ABANET from another X.25 PAD, like MacX25, you just need their address. From MacX25 you enter that address in the "Host Address" or "Called Address" field. Then, open the connection via a terminal communication tool (MacTerminal 3.0, White Pines Mac241, or the like). Their address will be understood by your local PDN provider's packet-switching equipment and your call request will be routed through whatever PDN networks are required to reach ABANET.

AppleShare: Processors, RAM, and User Limits

I understand that AppleShare is limited to 50 concurrent users in its current version, but what is the technical reason behind this seemingly arbitrary limit? I've heard something having to do with the number of sockets allowed per node and that each AppleShare user requires the use of two socket addresses? Can you explain?

This article has been archived and is no longer updated by Apple.
The AppleShare concurrent user limit is hard-coded, based on performance assumptions made about the number of users a given type of server could support. Depending on what type of Macintosh you have and its quantity of RAM, a certain amount of memory is allocated to support that number of users.

A 68000- or or 68020-based server with 1MB of RAM supports up to 25 users -- but a 68020 or "higher" CPU with 2MB or more of RAM lets AppleShare support up to 50 users.

A/UX: Monitoring Memory Use (8/94)

How can I see the MEMORY usage that is being given to UNIX background tasks, UNIX command shell tasks, the Macintosh Finder shell, and the Macintosh applications running within it?

I am trying to find the optimum amount of RAM to reduce the amount of paging and swapping.

For example, when configuring a system for 16MB of virtual memory, with 8MB of physical RAM, it is difficult to predict when swapping occurs. Running SoftPC in these conditions sometimes brings the machine to a halt because the Finder seems to be "swapped out".

This article has been archived and is no longer updated by Apple.
Currently, we don't know of any particular memory monitoring program for A/UX. However, in a CommandShell window the "pstat -m; sleep 5" in a "do while loop" may constantly report the current available memory.

From the Finder desktop, the "About This Macintosh..." DA from Apple Menu will display memory allocation information for all Finder Desktop programs including CommandShell.

To monitor the memory use for each component--like UNIX tasks, CommandShell, Macintosh applications, and so on under A/UX--you need a program that understands the A/UX kernel memory management, that can support simultaneous access by both 24- and 32-bit applications, and is compatible with the existing Macintosh OS Memory Manager. Such a program probably needs to hack /dev/kmem, /mac/bin/{mac24, mac32}, /mac/bin/startmac, and so on.

MacDFT: Frozen Screen and LOGMODE Frame Sizes

I have a Token Ring problem related to MacDFT. When configuration on the host changes, MacDFT doesn't work.

Configuration
Macintosh IIcx with Token Ring Card
AROSE Prep 1.1.1
Macintosh DFT 1.1

I am using my own LOGMODE table on the host. The following is copied from the file TCBMODE ASSEBLE R1. Here is the default logmode that works:

M2SDLCQ MODEENT LOGMODE=M2SDLCQ
FMPROF=X'03'
TSPROF=X"03'
PRIPROT=X'B1'
SECPROT=X'90'
COMPROT=X'3080'
RUSIZES=X'8587'
PSERVIC=X'028000000000185000007E00'

This is IBM's mode. Here is a different logmode that is unique to my site.

TBR3180 MODEENT LOGMODE=TBR3180

FMPROF=X'03'
TSPROF=X"03'
PRIPROT=X'B1'
SECPROT=X'90'
COMPROT=X'3080'
RUSIZES=X'87C7'
PSERVIC=X'028000000000000000000300'

The problem is that when I use my own logmode, the screen freezes the session, and the user has to do a terminal reset to return to normal. This problem is consistently reproducible. The same problem does not occur when using Avatar or MacIrma products.

This article has been archived and is no longer updated by Apple.
The system network administrator asked for the "I" and "T" frame sizes supported on our TokenTalk NB card, and this turns out to be the source of the problem. The frame sizes are fixed at 256 and can't be modified. You chose to provide multiple configurations for the frame sizes depending upon the user's needs. If you make the change to Apple's supported size, your system should work fine on the released version of MacDFT.

AppleShare PC: Minimum Files Needed for File Services

What is the bare minimum for AppleShare/PC files needed to access FILE SHARING only? The following is the list of files I am currently loading, and I need to free up at least 60K of RAM:echo off.

C:\\ASPC\\LSL
C:\\ASPC\\ENET3CII /NAME=ETHER$
C:\\ASPC\\AARP
C:\\ASPC\\ATALK
C:\\ASPC\\ASP_WS
C:\\ASPC\\AppleShare
C:\\ASPC\\MINSES
C:\\ASPC\\REDIR
C:\\ASPC\\ANET AUTO

Any chance I could take some of these out?

This article has been archived and is no longer updated by Apple.
You have the minimum files necessary for what you want. Depending on the type of hardware you are using, it may be possible to load some parts of AppleShare PC into high memory (you need a 386 machine with a minimum of 1MB of RAM). This would free up more than the 60K that you are looking for.

If you want to check the files you do have, you could re-run the Installer and specify file services only, that will install the minimum set.

MacX Under A/UX: When xcalc Doesn‘t Accept Keystrokes (4/93)

Article Change History

04/20/93 - REVIEWED
* For technical accuracy.

When running MacX under A/UX I noticed that I couldn't type to the xcalc client running under A/UX. However, both X for A/UX and eXodus handled the keystrokes.

This article has been archived and is no longer updated by Apple.
xcalc doesn't accept keystrokes when displayed in rootless style. This has been reported to A/UX Engineering. A workaround is to display xcalc in a rooted window, as you were doing with native X and eXodus.

Instead of this:

xcalc -display <yourmac>:0.0

Use this:

xcalc -display <yourmac>:0.1

The ".1" causes xcalc to be displayed in the rooted monochrome window. In this style, it seems to work fine. For more information on rooted versus rootless windows, refer to chapter 1, page 12, of the Apple MacX manual from the A/UX manual set.

This has been fixed in A/UX 3.0 and MacX 1.2.

Macintosh-to-HP/UX Connectivity

I have an HP9000 running HP/UX and a LocalTalk network with many Macintosh systems and connected by Farallon's PhoneNET StarController system. I would like to convert the LocalTalk system to run Ethernet (Farallon has the PhoneNET StarController EN, which should do the job).

However, HP's implementation of TCP/IP runs across 802.3 networks and not Ethernet. Our TCP/IP implementation (via MacTCP) pumps out Ethernet packets and not 802.3. I want to connect the Macintosh computers to the HP/UX system to do file transfer (no file conversion necessary), terminal emulation, and SMTP.

Can you suggest any third-party gateways that can convert Ethernet packets to 802.3 on an Ethernet-based StarController EN network? Do you see any potential implementation problem based on the PhoneNET StarController EN to HP/UX?
This article has been archived and is no longer updated by Apple.
The product of choice for this type of conversion seems to be the cisco router. If you want to translate HP 802.3 to Ethernet on the same cable, you can configure the cisco to do that. It's been in the product for three or four years. 802.3 to Ethernet was one of their original design goals.

If you want or need a bridge, HP bridges work fine with both Ethernet and HP 802.3 encapsulation. For more details, search the Technical Info library under "cisco."

TA44980_LaserWriter_Printing_on_Heavy_Paper_(TIL06437).pdf

LaserWriter: Printing on Heavy Paper

Can any LaserWriter print on 65-pound paper (card stock used on shelves)?

This article has been archived and is no longer updated by Apple.
The "LaserWriter II Owner's Guide" specifies the paper at:

16-lb. to 20-lb. photocopy or typewriter bond (60 to 80 g/m2) in normal mode; up to 36-lb. (135 g/m2) stock in manual mode with face-up tray open.

We don't know of a way to use a LaserWriter to print on 65-pound paper. The LaserWriter paper path will not support paper of that thickness, nor is there enough heat to fuse the toner through paper that thick.

You can, of course, use the LaserWriter to print labels and stick them to any thickness of paper. Labels as large as 8.5 X 11 are available.

Personal LaserWriter NT Software Switching

Is it possible to soft switch the Personal LaserWriter NT between PostScript and HP Emulation? The PostScript code for the LaserWriter IINTX doesn't seem to work.

This article has been archived and is no longer updated by Apple.
You are correct, the PostScript code for the LaserWriter IINTX for software mode switching does not work on the Personal LaserWriter NT. The "setsoftwareiomode" value, which is used in the LaserWriter IINTX to set the mode, is not defined in the Personal LaserWriter NT.

However, you can use software switching to switch the Personal LaserWriter NT temporarily from PostScript to HP LaserJet+ or Diablo emulation. To emulate the HP LaserJet+, send the following PostScript to the Personal LaserWriter NT:

```
statusdict begin
currentfile /hpcl emulate
```

To emulate the Diablo, send the following PostScript to the Personal LaserWriter NT:

```
statusdict begin
currentfile /Diablo emulate
```

This DOES NOT work the same way software switching to set the mode on a LaserWriter IINTX works. As soon as this job is completed, the Personal LaserWriter NT will change back to PostScript mode. Therefore, you must send this code at the beginning of each job with the job appended to it. To do this, you could put the previous PostScript code in a file, say "hpcl.ps". Then, to print a job in HP LaserJet+ mode from a PC, type:

```
copy hpcl.ps+filename.txt lpt
```

This would send the file you want printed in the same job as the PostScript code that switches the Personal LaserWriter NT to HP LaserJet+ mode. If these files are sent separately, the Personal LaserWriter NT will have already reset back to PostScript mode before the file to be printed reaches the printer.

As this PostScript must be sent with every job, a file cannot be printed straight from a program to the Personal LaserWriter NT. The file would have to be saved to disk, and then sent to the Personal LaserWriter NT as specified above.

You can also set the pushwheel switch on the Personal LaserWriter NT for HP LaserJet+ or Diablo emulation. Switch position 2 sets it to HP LaserJet+ mode, and switch position 3 sets it to Diablo mode.

Personal LaserWriter NT: How to Print IBM ECS Characters

Article Change History

05/18/93 - CORRECTED
* To correct PostScript code found in the article

Please give me some information about the use of the IBM Extended Character Set ECS in the Personal LaserWriter NT.

- Can you use ECS with standard Macintosh software (e.g., word processing)?

- Can you use ECS with SoftPC?

- How can we use ECS from a PC running AppleShare PC?

This article has been archived and is no longer updated by Apple.
The ECS character set in the Personal LaserWriter NT is implemented as an extension to Diablo emulation, as opposed to an independent PostScript font. In fact, it is designed to behave like the IBM PC Graphics ECS print wheel for Diablo 630 daisy wheel printers. This creates some interesting requirements for its use with different host computer environments and also imposes some limitations on how the special characters can be used.

Each of the three scenarios you list requires its own sequence of steps to print documents using ECS characters. Although the setup for each is different, the basic procedure is the same. It follows these basic steps:

1) Connect to the LaserWriter in PostScript mode.

2) Send code that enables ECS.

3) Switch to Diablo emulation.

4) Print the desired characters.

Unfortunately, Diablo emulation is not documented well in the "Personal LaserWriter NT Owner's Guide." Although code is provided to enable ECS, no mention is given of software mode-switching or the other options available for the DiabloDefaults dictionary. We'll cover the required basics here, and also provide a list of the different dictionary values and their meanings.

Setting the Personal LaserWriter NT to Diablo mode with the thumb-wheel switch requires disabling network access. Because of this, we'll avoid hardware switching in our examples and stick with software switching. We're assuming a Macintosh and Personal LaserWriter NT connected to an AppleTalk network along with an IBM PC using AppleShare PC.

Enabling ECS in the LaserWriter requires the following code. It can be entered in a text file and then downloaded using the psdump utility.

```
serverdict begin 0 exitserver
statusdict begin
DiabloDefaults /ecs true put
saveDiabloDefaults
```

This will persist, until it is forced back by the same code using "/ecs false" in place of "/ecs true". You needn't repeat his step, unless it has been intentionally reversed.

Now, we switch to Diablo emulation and send the desired text to be printed. Software switching of the Personal LaserWriter NT differs from hardware switching (and from software switching of the LaserWriter IINTX) in that it only persists until the end of the print job. Any Diablo text or ECS characters must be appended to the switching code or be treated as a separate print job:

```
statusdict begin currentfile /diablo emulate
This text will be printed as if the Personal LaserWriter NT
were a Diablo 630.
```

If the above lines were downloaded to the LaserWriter with psdump, the second two lines would be printed verbatim. If there were special ECS characters, those would be printed as well.

We can't show any of the actual ECS characters in this article, but we can show you how to generate them. The ECS character set is essentially an expanded version of the standard Diablo character set. The special characters lie in the ASCII ranges below 31 and above 126. The following Microsoft BASIC program creates a text file with the special characters in the high range of 127 through 255.

```
10 open "ECS_STUF.TXT" for output as #1
20 for i=127 to 255
30 print #1, chr$(i);
40 if (i-126)/70 = int((i-126)/70) then print #1, ""
50 next i
60 close #1
```

A similar HyperCard script could be used to create the file on a Macintosh.

```
on mouseDown
put "High ASCII ECS Chars" into filename
open file filename
repeat with i = 127 to 255
write numToChar(i) to file filename
if (i-126)/70 = (i-126) div 70 then write return to file filename
end repeat
close file filename
end mouseDown
```

To print these files, prefix them with the Diablo emulation PostScript code from above and download the result with psdump. The result should be a page with two lines of the high ASCII ECS characters.

A/UX 2.0: How to Customize Session Types

During the login phase, you can choose different logins (Session Type). How can I customize this environment -- to launch X, for instance?

This article has been archived and is no longer updated by Apple.

When the X11 Window System is installed, the X11 session automatically will be created in the /mac/lib/sessiontypes directory.

The code below shows how the X11 session is created from an X11.r resource file. The X11.r file is as follows:

```
/*
  * description file for X11 session type.
  */

resource 'STR#' (128) {
  {
/* The name that the user selects in the list box. */

     "X11";

/* The description of this session type. */

     "X11 is Apple's adaptation of the industry standard "
     "X Window System for A/UX. X11 is a pure X environment, "
     "and no Macintosh compatibility is provided.";

/* The command that gets executed for this session type. */

     "/usr/lib/X11/X";

/* Name of file to look for in user's home directory to run */
/* instead of command given above. */

     ".X11"

  }
};
```

Then the following commands create the X11 resource file:

```
/mac/bin/rez -i /:mac:lib:rincludes types.r X11.r
fcnvt -f -s Rez.out X11
rm -f Rez.out
```

With the above example, you can create your own session.

Macintosh Portable: Use the Sound Manager From 6.0.7

I have developed an application in C through which I can connect a Portable to one of a phone switches and establish a session with the switch and then play some background music on the Portable. This code has worked on numerous Macintosh II systems, but fails on the Portable (quits the application, returning to Finder without a warning).

The Portable has 2MB of RAM and System 6.0.5. I am using identical pieces of code on both machines and the toolbox calls are the same. Some have suggested that there may be a difference in the sound architectures of the Macintosh II family and the Portable family that requires different calls to the Sound Manager for the Portable.

This article has been archived and is no longer updated by Apple.
The Sound Manager prior to System Software 6.0.7 was known to have problems. Our first suggestion is to install 6.0.7 on the Portable. The new Sound Manager does have additional functionality. However, all previous interface calls are still valid. The new Sound Manager has been totally rewritten, providing a more robust tool.

Because the application appears to be working in certain environments, it would seem one of the problems of the old Sound Manager becomes obvious when used on the Portable. Using the new Sound Manager shipped with 6.0.7 should provide a solution.

LaserWriter: Macintosh SE Connection with ImageWriter Cable

I hooked up a LaserWriter IINT to a Macintosh SE for local printing using an ImageWriter cable, and it worked! Is this okay?

This article has been archived and is no longer updated by Apple.
When you connect to a LaserWriter in this fashion, you are in reality still running LocalTalk between the Macintosh and the LaserWriter. Although this works in most cases, it is not a supported configuration, and we do not recommend using it. Instead, use the proper cabling necessary to implement a LocalTalk connection between the LaserWriter and the Macintosh.

Apple IIGS: VGC and ROM Upgrade

Beginning August 1, 1987, two free component upgrades have been available to Apple IIGS owners. This REA program ended on 31 March 1995.

This article has been archived and is no longer updated by Apple.

Overview

These are the two component upgrades:

- A new ROM chip corrects minor problems and provides enhancements for future software releases.

- A new Video Graphics Controller (VGC) chip corrects video display problems that may occur in double hi-res and standard text modes.

Look at the first three digits of the serial number on the bottom of the Apple IIGS to determine which of the two upgrades your computer needs. (This is only a general guide, because a given computer may have already undergone modifications after leaving the factory. For more specific information, see the "Upgrade Part Numbers" section later in this article.) These are the guidelines:

- Computers with the first three digits of the serial number 704 or lower, generally require both the new VGC and the ROM upgrade.

- Computers with the first three digits of the serial number 705 through 724 (inclusive), generally require only the new ROM.

- Computers with the first three digits of the serial number 725 or higher, generally require neither of the upgrades.

Upgrade Part Numbers

Because some systems may have had logic board swaps since date of purchase, it's best to check the individual VGC and ROM numbers on the main logic board to be sure of which upgrade is required.

- Replace any ROM chip numbered 344-0077-A with the replacement part 344-OO77-B.

- Replace any VGC chip numbered AMI 344SOO46-1 or AMI 344SOO46-A with the replacement part AMI 344SOO46-3, IMP 344SOO46, or IMP 344S0056.

- VGCs numbered AMI 344SOO46-2 or AMI 344SOO46-B need no replacement.

The repair extension program number is 0LR853.

***** IMPORTANT NOTE *****

This program expired on 31 March 1995 and is no longer available under an REA program. However, you can purchase the VGC IC and ROM chip as separate items. In order to pull the VGC chip off the logic board, you will also need the VGC IC extraction tool. Here are the parts you need:

342-0077 ROM, Apple IIGS
344S0046 VGC, Apple IIGS
076-0246 VGC IC Extraction Tool

LaserWriter 6.0.1: Changes that Address Timeout Problems

When LaserWriter 6.0.1 driver came out, there was a specification sheet describing what was in 6.0.1 and how it helped resolve network timeout problems with LaserWriter IINTs and LaserWriter IINTXs. Can you summarize what it said about timeouts?

This article has been archived and is no longer updated by Apple.
The LaserWriter 6.0.1 driver changed two timer settings:

Previously, if part of a print job, a packet, intended for the LaserWriter got lost and wasn't resent in time to reach the LaserWriter within 30 seconds, the print job would be flushed. This low-level timer was eliminated. (Now the PostScript job will timeout after 5 minutes if a packet is "permanently" lost.)

Additionally, if the printer was busy printing something, like multiple copies of a complex document, the connection timer could time out. Now, the Macintosh waits for 3 minutes (previously 2) for the printer to respond before timing out.

The first job is much more likely to occur on large networks where routers are used. The second problem is more prevalent with printing complex documents on the slower LaserWriters (e.g., a LaserWriter IINT as compared to a LaserWriter IINTX).

Macintosh Portable: Touchbase External 9600-Baud Modem

I'm seeking a 9600 baud internal modem for the Macintosh Portable that is compatible with the Shiva NetModem v.32.

This article has been archived and is no longer updated by Apple.
As of October, 1990, we haven't heard of any internal 9600 baud modems for the Macintosh Portable. However, Touchbase Systems just announced an external portable modem, the WorldPort 9600.

The WorldPort 9600 is a portable V.32, 9.6Kb self-powered modem for laptop computers. The WorldPort 9600 supports full-duplex synchronous and asynchronous communications. The 8-ounce modem contains an EIA-232 port for direct connection to a laptop. It runs under its own 9V battery or via an optional external AC adapter

The 9600 features Trellis coding, echo cancellation, fallback speeds from 300 bits to 4.8 bits and MNP Class 4 error correction. It supports the Hayes AT command set and CCITT V.21, V.22, B.22bis, V.23, and Bell 103 and 212A standards.

MacDFT: To Print Screen, Turn Background Printing Off

I am having problems printing screens with MacDFT 1.1. No matter what I do, the "Print Screen" option remains dimmed.

This article has been archived and is no longer updated by Apple.

To work around a bug in the Print Monitor, MacDFT does not allow "Print Screen" to be selected when background printing is on. To print screens with MacDFT, turn background printing off.

A/UX: "vn_rele" Panic Message (9/94)

When I log out of a session on A/UX, I get the message:

panic: vn_rele

This happens on a Macintosh IIfx with miroGRAPH graphics board, Ethernet NB Card, 200MB Conner Drive (one UNIX partition, c0d0s0, partitioned with SilverLining).

What does the above panic message mean, what are its causes, and what do I do about them? These other panic messages were encountered when doing an "fsck" on the file system after the above panic message: "panic: free freeing free block" and "panic: ialloc_dup alloc".

The display on the above machine changes its size on booting A/UX (the menu bar gets squeezed downwards). Is this just a problem with the third-party monitor card? Does A/UX reset the monitor card on booting the kernel?

This article has been archived and is no longer updated by Apple.
It seems that you had a UFS root file system problem on the Conner hard drive.

The above "panic: vn_rele" message occurrs when the A/UX UFS file system tries to do a vn_rele function (release a vnode and decrement the reference count) to maintain its file system data structure. Panic occurs when the reference count reaches to 0. Both the "free freeing free block" and "ialloc_dup alloc" panic messages indicate that there is a bad free-block list and duplicate inode allocations in the UFS super block.

We don't know the parameters used when the UFS root file system was created on the Conner drive. These parameters (like the number of sectors, tracks, and cylinders) must be specific to the Conner drive.

If the parameters used to create a UFS file system do not match the drive, we suggest that you rebuild the UFS file system with the correct values. Otherwise, try to "fsck" the root file system (you can do the "fsck" in #startup mode) to make a clean root file system.

We haven't seen the menu bar squeezed problem on our third-party monitor while A/UX is booting. Check with the vendor about this problem. Yes, A/UX does a reset on the monitor card when the A/UX kernel is loaded.

Pascal III: Intrinsic Units

This article has been archived and is no longer updated by Apple.
Intrinsic Units in Pascal allow the programmer to write and compile code in modules. The progammer can put the modules in a library; several different programs can then use them without a separate linking step. The unit is automatically loaded with the program code file when the program is executed.

The following is a simple example of how to write an intrinsic unit. It is a supplement to the information in chapter 14 of the Programmer's Manual.

First let's enter the unit. This unit has one function that asks for an integer number and returns that number doubled. From the editor, enter:

```
UNIT LIB2;
INTRINSIC CODE 10;

INTERFACE
FUNCTION DOUBLE (NUM:INTEGER):INTEGER;

IMPLEMENTATION
FUNCTION DOUBLE;
BEGIN
DOUBLE := NUM + NUM;
END;

BEGIN
WRITELN ('LIB2 INITIALIZATION');
END.
```

Save the file as LIB2, quit the Editor and compile the unit.

Now put the unit in a library. We suggest you use a program library for this test so that you won't have to modify the SYSTEM.LIBRARY. Here's how to do it:

```
Execute /PASCAL3/LIBRARY
The destination will be TEST2.LIB
The source is LIB2.CODE
Enter "=" to copy the entire codefile into the library
Enter "Q" to save the library and exit the program
Press return when asked for Notice?
```

When that's done, go back to the Editor and enter:

```
PROGRAM TEST2;

USES {$USING TEST2.LIB} LIB2;

VAR INT:INTEGER;

BEGIN
READLN (INT);
WRITELN (INT, ' times 2 equals ', DOUBLE (INT));
END.
```

Save the file as TEST2 and quit the Editor. Compile the program. The unit will be loaded automatically when the program is executed.

DAL: Model 204 and IMS Databases Not Supported

Is there a database product called "Model 204" which runs on IBM mainframes? If so, is there any way for Data Access Language (DAL) to connect to it now or in the future? Can (or will) DAL interact with IMS data bases?

This article has been archived and is no longer updated by Apple.

Model 204 is an on-line and batch DBMS built on a proprietary inverted file access method. The system includes an integrated data dictionary for flexibility in defining and protecting data acquisition. An inverted file, relational system, like Model 204, can support applications that require very large data bases, high transaction volumes, and a large number of concurrent users--all with a high degree of flexibility and efficiency. In that respect, it differs significantly from the standard relational DBMSs that are notoriously slower and more cumbersome to manipulate.

The Model 204 system is fully integrated, with its own query language and communications interfaces to CICS, CMS, and Thorn EMI's Shadow II. It comes with its own 4GL and can support most popular third-generation languages.

Model 204 can also be configured in a mainframe-microcomputer environment with its PC/Workshop product. It also supports a LAN environment.

Currently, DAL supports neither Model 204 or IMS database. There is no plan in the near future for supporting these two products.

Macintosh LC: PDS-Based Coax Card

Is there a coax board for the Macintosh LC? With its new form factor of 3 X 7 inches, none of the earlier cards fits. (Tri-Data Netways won't be used.)

This article has been archived and is no longer updated by Apple.
We assume that many vendors are looking into this, including Avatar as in the following article from "Apple Intro News". With Avatar Corporation's new MacMainFrame Series, Macintosh LC computer users can connect with IBM 3270 mainframes.

"The MacMainFrame Series for the Macintosh LC includes the MacMainFrame Coax Workstation, which offers a Coax-attached internal card that fits into your Macintosh LC 020 Processor Direct Slot for direct connection to an IBM 3270 network. It provides either 1-session CUT or 5-session DFT emulation. The MacMainFrame Coax Gateway provides Macintosh work groups with access to up to five IBM host sessions.

"The MacMainFrame Token Ring Workstation provides a direct connection to a Token Ring network giving you access to up to 8 IBM 3270 sessions. The MacMainFrame Token Ring Gateway allows Macintosh users in an AppleTalk environment to run host applications on an IBM host that resides on a Token Ring network.

"The MacMainFrame SDLC Workstation allows you to directly access host information over a local or remote Synchronous Data Link Control (SDLC) connection. The MacMainFrame SDLC Gateway provides a Macintosh work group in an AppleTalk environment with local or remote access to an IBM host over an SDLC connection."

Macintosh: FTP Servers

Is there a product that supports an FTP server on the Macintosh that runs in the background? We have a requirement to send files from TCP/IP equipped VAX and UNIX machines to a Macintosh in the background. Does the Apple Comm Toolbox support this? Does the Comm toolbox support socket-level programming? What other products support socket-level programming?
This article has been archived and is no longer updated by Apple.
The CommToolBox does not provide support for socket-style programming while using MacTCP. There are currently no commercial products that provide a socket-style interface for MacTCP.

There are several commercial products that provide an FTP server for the Macintosh.

A/UX: How to Rebuild Desktop (5/95)

How do you rebuild the desktop under A/UX?

This article has been archived and is no longer updated by Apple.
Follow these steps to rebuild the desktop:

1) Login to the A/UX Command Shell as root user.

2) rm /mac/sys/'System Folder'/.fs_cache

3) rm /mac/sys/'System Folder'/*Desk*

4) Logout and Login to the A/UX Finder environment.

5) When you see a dialog asking "Are you sure you want the desktop rebuilt..." click OK to rebuild the Desktop Database. Rebuilding the desktop may take some time, depending on the amount of local disk space attached.

An alternative to this method follows:

1) Logout and Login to the A/UX Finder environment

2) After the "Starting session for username..." dialog disappears, press and hold both the "Option" and "Command" keys until you see a dialog asking "Are you sure you want the desktop rebuilt...".

3) Click OK to rebuild the Desktop Database. Rebuilding the desktop may take some time, depending on the amount of local disk space attached.

Black & White Displays: Bibliography

When the Macintosh first came out, Apple cited studies indicating that a black on white display was superior to white/green/amber on black ones. The reasoning had to do with easier focusing due to a brighter screen closing the iris, and less adjustment required of the eye when looking between paper and screen. Can you cite the references we used to support these conclusions?

This article has been archived and is no longer updated by Apple.
There were two studies in 1980, and the information can be found in the following books:

* Radl. "Ergonomic Aspects of Visual Display Terminals"; London Taylor and Francis, 1980.

* Bauer and Cavonius. "Improving the Legibility of Visual Display Units through Contrast Reversal"; 1980.

There is also a newer book that summarizes the information in the other two books:

* Etienne Grandjean. "Ergonomics in Computerized Offices"; 1987.

AppleTalk Network: Remote Dial-In Access from MS-DOS

I want to add a remote on-campus PC-compatible to our AppleTalk network, via a Northern Telecom SL-1. We're planning to install a Liaison router on the LocalTalk side. Is there an MS-DOS-based, asynchronous, dial-up Liaison client product available for the PC (like the Macintosh version)?

This article has been archived and is no longer updated by Apple.
With DOS Dial-In (a Shiva product) a remote PC can dial into a LocalTalk network and access files on a TOPS server or print to a LaserWriter. You will need the following at the remote site:

- PC with a COM port

- a modem (9600 bps recommended)

- DOS Dial-In software

- TOPS/DOS 3.0 software (FlashCard not needed)

On the network you need:

- a Macintosh or PC running with a TOPS volume published and either

- a Shiva TeleBridge or EtherGate with the same make and model modem; or

- IF you are using a V.32 Hayes-compatible modem on PC, a Shiva NetModem V.32

As of October, 1990, DOS Dial-In supports TOPS file-sharing only. AppleShare will be added very shortly. You can currently access E-mail with DOS Dial-In as well. You should use QuickMail, Microsoft Mail, or InBox. You need to use the TOPS drivers on the remote PC to use these mail packages with DOS Dial-In.

Solana also has a product, "PC NetAccess," through which MS-DOS computers can dial-in to an AppleTalk network via their R-Servers.

Editor's Note 22 June 1992: Solana has discontinued business to our knowledge, so we are unable to refer you to them directly for further information.

Pascal III: Regular Units

This article has been archived and is no longer updated by Apple.
Regular Units in Pascal allow the programmer to write and compile code in sections. The programmer can then link the sections to form a single code file that will run without the need to refer to a library. The following is a simple example of how to write a regular unit. It is a supplement to the information in chapter 14 of the Programmer's Manual.

First let's enter the unit. This unit has one function that asks for an integer number and returns that number doubled. Enter the editor and enter:

```
UNIT LIB1;

INTERFACE
FUNCTION DOUBLE (NUM:INTEGER):INTEGER;

IMPLEMENTATION
FUNCTION DOUBLE;
BEGIN
DOUBLE := NUM + NUM;
END;

BEGIN
WRITELN ('LIB1 INITIALIZATION');
END.
```

Save the file as LIB1, quit the Editor and compile the unit. Now enter the program that will use LIB1:

```
PROGRAM TEST1;

USES {$USING LIB1.CODE} LIB1;

VAR INT : INTEGER;

BEGIN
READLN (INT);
WRITELN (DOUBLE (INT));
END.
```

Save this file as TEST1, Quit the Editor, and Compile TEST1. Now you have the code file for the unit and the program. The next step is to link them together. Enter L from command mode to get into the Linker.

```
The Host File is TEST1
The Lib file is LIB1
Just press return for the next two questions
The output file will be TEST1
```

Now TEST1 is ready to execute. Any time you change or re-compile either TEST1 or LIB1 you will have to re-link them.

Macintosh LC: Compatibility W/ Selected Software (1 of 3) 1/93

To help ensure that you have an appropriate version of the application program you intend to use, Apple Computer, Inc., has compiled this list from information received from certain software developers. These developers have recommended certain versions of their software for use with the Macintosh LC computer. This is by no means a comprehensive list of programs or versions of programs that are compatible with the Macintosh LC.

Please contact your dealer or the software developer if you have any questions. They can help you identify the newest version of a particular program or tell you how to upgrade your current version if necessary. For best results, we recommend you use the latest versions of software and hardware products with your Macintosh LC.

A/UX: Setup for Modem Autoanswer (8/94)

What setting is necessary to have a 1200 baud modem autoanswer from the modem port?

This article has been archived and is no longer updated by Apple.
In A/UX, if you have a problem talking with the modem, first try running stty -g /dev/tty0 -modem. This will disable modem control on the modem port. In the /etc/inittab subdirectory, make two changes to the line for the modem port as follows:

change the "off" to "respawn"

change the "at_9600" to "mo_1200"

Note: If you have a 2400 baud modem, the last expression should be "mo_2400".

A/UX: Giving the System its Domain Name (6/93)

Why doesn't my system know its domain name?

This article has been archived and is no longer updated by Apple.
This is a consequence of having an empty /etc/inittab file. It happens because the /etc/sysinitrc file is not being executed. Once you recover the /etc/inittab file, the system domain name will be defined correctly.

A/UX: How to Adjust the Kernel Parameter NUBUFS

Article Change History

08/31/92 - REVIEWED

* For technical accuracy.

I want to connect to Ethernet. The figures for a 5MB configuration were typed

in. Running the command

netstat -r

brings up the message

mexpand returning 0

This article has been archived and is no longer updated by Apple.

A request to allocate memory to use for memory buffer space was denied. Wait a

short while, and see if the condition clears up before rebooting. You may

also consider increasing the size of the buffers available; adjust the kernel

parameter NUBUFS. To do this, follow these steps:

1) Log in as "root" and bring the system down into single-user mode.

2) Execute "kconfig -av | grep NMBUFS". It should return the network

memory buffers configured in the kernel. A/UX is distributed with

NMBUFS=500.

3) Type "kconfig -n /unix"

4) Type "NMBUFS=" followed by the number you would like to increase it to

followed by a carriage return. Try increasing the number of mbufs to

1000; type "NMBUFS=1000"

5) Type a Ctrl-D to exit kconfig. The shell prompt will reappear.

6) Execute "sync; sync; sync; reboot". The system will sync and reboot

itself. Bring it back up.

Pascal II: Intrinsic Units compiler options RESIDENT & NOLOAD

You can get Apple Pascal version 1.1 to treat intrinsic units as segments (overlays) by using the noload (*$N+*) and the resident (*$R unit name*) compiler options. Units specified by these options are read in from the disk only when a reference is made to code contained within the unit. When the calling procedure is exited and all active references to the unit have been resolved, the unit is "swapped out" and the memory range can be used for other code segments. For more details on the use of these options, refer to pages 66-67 of the Pascal Language Reference Manual, and the Language Manual addendum.
This article has been archived and is no longer updated by Apple.
The unit code with the noload option will remain in memory until the calling procedure is exited. This may result in a stack overflow (out of memory) if control never exits from such a unit after it is called repeatedly from inside the same procedure. This is a known problem, and can be avoided by specifying the unit as "Resident" within that procedure or segment. Calling the unit from within a different procedure will also remedy this. The following examples illustrate this situation:

EXAMPLEA below will generate an out of memory STACK OVERFLOW error by repeatedly loading APPLESTUFF.

```
PROGRAM EXAMPLEA;
USES APPLESTUFF;

VAR I: INTEGER;

BEGIN (* MAIN PROGRAM *)
(*$N+*)
WRITE ('NUMBER OF WORDS AVAILABLE AT START OF PROGRAM : ');
WRITELN (MEMAVAIL);
FOR I:=1 TO 100 DO BEGIN
WRITELN (I,' ',MEMAVAIL,' WORDS');
NOTE (25,1) (* APPLESTUFF MUSIC ROUTINE *)
END;
WRITELN ('PROGRAM COMPLETED SUCCESSFULLY')
END. (* MAIN PROGRAM *)
```

EXAMPLEB uses the RESIDENT OPTION to prevent APPLESTUFF from being reloaded.

```
PROGRAM EXAMPLEB;
USES APPLESTUFF;

VAR I: INTEGER;

BEGIN (* MAIN PROGRAM *)
(*$N+*)
(*$R APPLESTUFF *)
WRITE ('NUMBER OF WORDS AVAILABLE AT START OF PROGRAM : ');
WRITELN (MEMAVAIL);
FOR I:=1 TO 100 DO BEGIN
WRITELN (I,' ',MEMAVAIL,' WORDS');
NOTE (25,1) (* APPLESTUFF MUSIC ROUTINE *)
END;
WRITELN ('PROGRAM COMPLETED SUCCESSFULLY')
END. (* MAIN PROGRAM *)
```

EXAMPLEC uses individual procedure to call APPLESTUFF routine, which allows unit to be released and then reloaded.

```
PROGRAM EXAMPLEC;
USES APPLESTUFF;

VAR I: INTEGER;

PROCEDURE PLAY;
BEGIN WRITELN (I,' ',MEMAVAIL,' WORDS');
NOTE (25,1) (* APPLESTUFF MUSIC ROUTINE *)
END;
```

```
BEGIN (* MAIN PROGRAM *)
(*$N+*)
WRITE ('NUMBER OF WORDS AVAILABLE AT START OF PROGRAM : ');
WRITELN (MEMAVAIL);
FOR I:=1 TO 100 DO PLAY;
WRITELN ('PROGRAM COMPLETED SUCCESSFULLY')
END. (* MAIN PROGRAM *)
```

A/UX: Network Reads Take Longer than Writes

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

Reading data over a network takes longer than writing. The code writes data from a Macintosh II over a dedicated network to another Macintosh II running A/UX. By the time the write is done on the server, the client is only about 80% done.

This article has been archived and is no longer updated by Apple.
Engineering believes that reading takes longer because after the data is taken from the network, it has to go through the IP, TCP, or UDP translation and then to the system read buffer. As a solution, try increasing NBUFS size.

800K Macintosh Disk: Sector and Track Info

I have three questions about 800K Macintosh disks:

1) How many sectors are there per side?

2) Is the top or the bottom of the disk used first for data storage?

3) What are the sync lengths of the tracks?

This article has been archived and is no longer updated by Apple.
1) The table below states the formatted capacity of the 800K media:

800K Disk Specifications

Bytes per Sector 512
Tracks per Side 80
Sectors per Track
Tracks 00-15 12
Tracks 16-31 11
Tracks 32-47 10
Tracks 48-63 9
Tracks 64-79 8
Sectors per Side 800
Sectors per Disk 1600
Bytes per Side 409600 (400K)
Bytes per Disk 819200 (800K)

2) The bottom of the disk is side 0; the top of the disk is side 1. The first sector, block 0, is on track 0 of side 0. The last sector, block 1599, is on track 79 of side 1.

3) A sector can be divided into four major sections. These are the header sync field, the header field, the data sync field, and the data field. These fields combined add up to 733.5 code bytes minimum.

Header Sync Field (6.25 bytes + sync overhead):

5 bit slip FF's minimum (FF,3F,CF,F3,FC,FF)

The header sync fields contain a pattern of ones and zeros that synchronizes the hardware state machine with the data on the disk. The header sync and headers field are written only when the disk is formatted. The formatter should make this field as large as possible, because this field buffers expansion of the previous sector's data field due to speed variation of the drive.

Header Fields (11 bytes):

The header field identifies the sector. The sub-fields are:

D5 AA 96 address marks: this identifies the fields as a header field
Track encoded low 6 bits of track number
Sector encoded sector number
Side encoded high 2 bits of track number and side bit:
decoded bit 5=0 for side 0, 1 for side 1
decoded bit 0 is the high-order bit of the track number
decoded bits 1-4 are reserved and should be 0
Format encoded format specifications:
decoded bit 5=0 for single-sided formats
decoded bits 0-4 define format interleave:
standard 2:1 interleave formats have 2 in the field

Checksum checksum formed by exclusive 'or' in the track, sector side, and format fields
DE AA bit slip marks: this identifies the end of the field
Off pad byte where the write electronics were turned off

Data Sync Field (6.25 bytes):

5 bit slip FF's (FF,3F,CF,F3,FC,FF)

The data sync field contains a pattern of ones and zeros that synchronizes the state machine with the data on the disk. This field is written whenever the data field is written.

Data Field (710 bytes):

The data field contains the actual data in the sector. The sub-fields are:

D5 AA AD data marks: this identifies the field as a data field
Sector encoded sector number
Encoded Data 524 bytes encoded into 699 code bytes; the first 12 data bytes are typically used as a sector tag by the operating system, and the remaining 512 bytes are used for actual data.
Checksum a 24-bit checksum encoded into 4 code byte
DE AA bit slip marks: this identifies the end of the field
Off pad byte where the write electronics were turned off

AppleTalk for VMS 2.1 and 3.0: Compatibility with VMS 5.4

Has AppleTalk for VMS 2.1 & 3.0 been tested for compatibility with VMS 5.4?
This article has been archived and is no longer updated by Apple.
AppleTalk for VMS 2.1 was not tested with VMS 5.4, because VMS 5.4 was not released at the time version 2.1 was tested. However, AppleTalk for VMS 2.1 should work under VMS 5.4.

There is a larger issue here that ties into your question about AppleTalk for VMS 3.0. In fact, there is only one choice, and that is AppleTalk for VMS 3.0 (as part of PATHWORKS, formerly DEC LanWORKS). Version 2.1 was an interim release intended solely to provide AppleTalk Phase 2 compatibility until version 3.0 was released. AppleTalk for VMS 3.0 works under VMS 5.4, and that is the current VMS product superseding all other releases.

If you're running older, AppleTalk Phase 1, versions of AppleTalk for VMS, you should start moving toward AppleTalk Phase 2 and AppleTalk for VMS 3.0. The only potential difficulty here is if you have products that require the AppleTalk for VMS 2.x API. In this case, you can go to AppleTalk for VMS 2.1 until those products have been revised to support the new API of AppleTalk for VMS 3.0.
Published Date: Feb 18, 2012

DAL: Using $maxrows and SELECT Statement

I have PATHWORKS (LanWORKS BL/4) running on our MicroVAX 3400. The DAL server is version 1.2. If I go into IDAL, and set $maxrows to 0, a select statement returns nothing. My understanding is that the $maxrows is supposed to enable an an return unlimited amount of data.

This article has been archived and is no longer updated by Apple.
We assume that you also issued the "printall;" statement after the "select" statement. Otherwise, you will not see anything printed.

The System Variables $maxrows is initially set to null. Null is not 0 (zero). To set $maxrows to the initial value of null, you should set it to $null.

When $maxrows is set to a non-null value, the SELECT and FETCH statements stop fetching data from the database when they reach the number of rows specified by $maxrows. Setting $maxrows to 24, for example, yields a 24 rows of database results without waiting for an entire query to complete. Setting it to 0 will result in zero rows.

Same-Size Images Not Possible with Different Resolutions

I am writing medical-imaging software and want to connect two 19-inch monitors with different resolutions.

I have assumed that if one monitor has twice the resolution as the other, the object will be half the size on the higher-resolution monitor. Is there is a way, within the Macintosh OS or via a third-party utility, to have an object display the same size on both screens despite twice the resolution on one monitor?

This article has been archived and is no longer updated by Apple.
The QuickDraw graphics model does not provide a mechanism that allows for display systems (card and monitor) with different dots per inch (dpi) resolutions to display an image at the same size. QuickDraw assumes a display system has a resolution of 72 dpi. This means that a 2-inch square (144 by 144 dpi) on a Macintosh Plus screen (72 dpi) will be an 2.09-inch square on the AppleColor High-Resolution RGB Monitor (69 dpi).

OfficeVision and Macintosh Connectivity: PIXI

I am looking for information on Macintosh-to-OfficeVision connectivity.
This article has been archived and is no longer updated by Apple.
There is a product for Macintosh-to-OfficeVision (and DISOSS) connectivity called PIXI (Personal Services Import Export) from IMI Computing. The product reportedly works in conjunction with DCA's MacIrma product. Its features include:

- Uploading and downloading Personal Services in-basket or filing cabinet entry(s) to the Macintosh. It also provides file transfer with both OfficeVision/MVS and Personal Services/CICS.

- Binary files can be transferred in native form for filing or distribution through Personal Services or DISOSS.

- PIXI MacIrma determines the document type as either RFT, EDITABLE, or PC FILE depending on the contents of the data. Macintosh ASCII files are automatically converted to EDITABLE if required. Macintosh RFT files are shared with other users unchanged (as RFT).

The product requires DCA's MacIrma hardware and APIs. On the host, you must also install the standard PIXI host component.

TA45023_Multiple_System_Files_on_One_Macintosh_An_Update__(TIL06498).pdf

Multiple System Files on One Macintosh: An Update (12/94)

Under Macintosh Operating Systems 5.x and 6.x, multiple system files on a single volume virtually guaranteed file structure and performance problems. However, under 7.x it doesn't seem so demonstrable. Moreover, utilities like System Switcher suggest that there are now toggles to enable and disable a system file. I've seen a number of users who archive, sometimes deliberately, multiple system files on a volume, with or without such utilities. Are there known risks in doing this, and does Apple have a position regarding this practice?

This article has been archived and is no longer updated by Apple.
We still recommend only one System Folder per volume. We are aware of some potential risks involved with multiple System Folders on one volume. They are:

* Confusion - It is very easy to become confused, either for the user or for a third party application, with the presence of more than one System Folder on the hard drive.

* Disk Cache - In rare instances, information in the Disk Cache may not get written to the hard disk before restarting. If you were blessing a System Folder before restarting, then your Macintosh may not recognize that it has a System Folder.

* Hard Disk Problems - In some instances, users have experienced low level hard disk directory problems, which were heightened by having multiple System Folders. In these cases, a Macintosh typically tried to load Extensions, Control Panels, and Preferences from an unblessed folder, and not from the blessed System Folder.

* Third Party Utilities - Third party utilities for blessing or unblessing multiple System Folders alter information in the hard disk directory's boot blocks. This is not supported by Apple and may cause problems.

If a user, for whatever reason, needs to have multiple System Folders, it is critical that the other System Folders be deblessed correctly, as follows:

1) With System 7.0 and later, move the System file to the Preferences Folder (hiding the System file in this way deblesses the System Folder).

2) Close the System Folder and verify its state before restarting. A blessed System Folder has a Macintosh in its icon. A non-blessed System Folder does not.

3) Rename the deblessed System Folder to any name other than "System Folder".

Macintosh Chooser: How It Displays Names

I am designing some AppleTalk-based services and need to know how the Chooser "sorts" these items:

1) For a network "object" (like LaserWriter or AppleShare), the display of network resources accessible to you.

2) For a specific AppleShare server, the display of Volumes accessible to a user.

It appears that none of these lists is alphabetical (though life would be simpler for network designers if they were). I'm hoping that by better understanding how it DOES work, we can choose our assortment of network and volume names more intelligently so the appearance to users is more consistent.

This article has been archived and is no longer updated by Apple.
1) For System 6 and earlier, the Chooser does not sort the names at all; they are displayed in the order that they are received by the NBP lookup request. Under System 7, the list is alphabetical.

2) At the server, devices are displayed in Finder order: startup volume first, followed by SCSI drives in descending order of SCSI address, followed by devices connected via the drive port in the order returned by the getVolInfo call. At the workstation, the devices are displayed in exactly the opposite order, with the startup volume at the bottom of the list.

Applesoft: OUT OF MEMORY Errors

There are only two ways to run out of memory in Applesoft. The most common reason for this error is either that your program is too large or it's using too many variables.
This article has been archived and is no longer updated by Apple.
The solution: trim down your program, keep the data on a disk, or chain your program in from the disk in segments.

The less common cause of this error is stack overflow. This problem is easily spotted, since after you receive the OUT OF MEMORY error, PRINT FRE(0) will tell you that there is still free memory. The 6502 stack, though, which Applesoft uses to save its recursive subroutine calls, is a limited resource; it's this stack that your program is overloading. Your program is overloading this stack in one or more of the folowing ways:

1. Too many FOR-NEXT loops
2. Too many GOSUBs
3. Excessively complex mathematical or string functions
4. GOSUBs with no RETURN
5. Improper recovery in ONERR GOTO routines
6. CALLs or interrupts that don't restore the stack properly

The effects of these functions are cumulative, so a combination of them could be causing your error.

Items one through four commonly occur in very complex programs. If one or more of these items is the cause of your problem, you can implement a program-controlled restart by executing the Applesoft routine CALL 54915; this routine clears the stack without clearing the variables by eliminating all pending FOR-NEXT loops, GOSUBs and formulas. Items one through four, though, have to do with your program structure, so when your program is cleanly structured you shouldn't have problems overloading the 6502 stack.

If a stack overflow is caused by running a cleanly-structured program, then that implies that the overflow is being caused by items five and/or six.

If you're using ONERR GOTO, carefully read pages 81, 82 and 136 of the (green and white) Applesoft BASIC Programming Reference Manual. There are two correct ways to leave the ONERR GOTO routine:

(1) use a RESUME so Applesoft can take care of the stack and re-execute the statement that caused the error
(2) use the stack recovery routine on page 82 or 136 before any GOTO statement.

(The example on page 136 is easier to implement.) If you're using Applesoft in ROM, replace the routine on page 136 with CALL -3288 and no POKEs.

When Applesoft executes a CALL, it does a 6502 JSR to the specified address. Other routines, such as those that handle interrupts from a peripheral card, also involve the 6502 stack. It's up to you to leave the stack the way you found it--so if you use any of these routines, make sure that you remove any bytes the pushed onto the stack so that the 6502's internal registers are maintained.

Macintosh Portable: PDS Manual Correction

Article Change History

10/29/92 - REVIEWED
* To indicate that problem has been corrected in the manual

Is there a problem with figure 13-5 (a diagram of the Macintosh Portable 68000 Direct Slot) on page 280 of "Designing Cards and Drivers for the Macintosh Family"? In a real Macintosh Portable, the PDS connector is soldered on the board rotated 180 degrees.

I've heard the connector should be soldered as described in the book, which is the official way. Which one is correct, the book or the Macintosh?

This article has been archived and is no longer updated by Apple.
The manuals ("Guide to the Macintosh Family Hardware", second and third editions, and "Designing Cards and Drivers for the Macintosh Family", second edition) are in error. The signals and signal descriptions are correct, but the key for the slot is off by 180 degrees (that is, columns A and C should be swapped, as should be rows 1 and 32).

The manual "Designing Cards and Drivers for the Macintosh Family", third edition, has been updated and the Macintosh Portable PDS diagram has been corrected.

HyperCard: HFSCopy External

Article Change History

09/01/92 - REVIEWED
* For technical accuracy

I am developing a HyperCard front end for software distribution via AppleShare servers and using the HFSCopy XFCN to copy files from servers to users' hard drives. I have also made stacks that do validation and audit trails (including MS Mail API) and log the user onto the server, based on certain access privileges. After logging on the user has to drag down the folders from the server manually. This may have to be the solution if the stack can automate the "copy."

HFSCopy works great the first time, but the next time it is executed, it won't work with a duplicate folder name on the user's hard disk. Is there a simple solution to this? Or do I have to verify the user's folders every time and/or rename the existing folder to "<folder name> old" or something like that?

How can I use HFSCopy without knowing the name of the destination hard drive? I don't want to require users to enter the name of their hard drive or the script to search for the volume name. A wildcard does not seem to work. I would like HyperCard to do the HFS Copy to the HyperCard launch volume. HyperCard knows where it is being launched from, so I need to tell the script this information. How can I access this information?

This article has been archived and is no longer updated by Apple.
You're right: the HFSCopy XFCN does not replace a folder with the same name. It does, however, return an error that you can check, as a way to work around this. Error -48 indicates a duplicate filename. You could write a script that uses a few XFCNs to index through the folder that you want to replace, deleting each of the files in the folder until the folder is empty, and then deleting the folder. Once this is done, you could then call the HFSCopy XFCN again, asking for the original folder. Because the folder no longer exists on your local disk, it will be copied successfully.

There are two XFCNs beyond HFSCopy that would help: FolderContents and DeleteFile.

The FolderContents XFCN returns the files and/or folders contained in a specified folder. Its syntax is:

FolderContents(Pathname, Ã,"Files"|"Folders"|"Both"╚Ã"noDialog:"errorGlobal╚)

where Pathname is a path to a folder to examine and parameter 2 is the literal string "Files", "Folders", or "Both".

This XFCN returns a carriage return delimited list (one file/folder per line) of all files, folders, or both files and folders (as per parameter 2) within the specified directory. The names of all folders will end in ":". The default is to list "both" files and folders. (The next version will be A/UX compatible.)

The third XFCN is DeleteFile, which deletes the file you specify. Specify the full pathname, as with the other two XFCNs. To delete a folder, that folder must be empty and you must trick the XCFN into thinking that the folder is a file. Therefore, delete everything in the folder, then call this XCFN once more using the folder name as a file name. In other words, where you would usually specify a folder name like "Hard Disk:folder1:", in this case, you omit

the last colon and pass the parameter "Hard Disk:folder1". Thus, DeleteFile will think the folder is a file, and--as long as the folder is empty--will delete it. Remember that if there are folders within folders you must work your way from the deepest folder out, deleting files and folders as you go.

To get HyperCard's full pathname, use the HyperCard command "the long name of stack home". From the result, you can derive the information you need.

A/UX: X Window System, MacX Performance Help

I am running some performance benchmarks on the A/UX implementation of the native X Window System and MacX. I cannot reproduce some favorable benchmarks that I read about in "Digital Review." I need some specific, concrete steps that I can take to optimize A/UX for running native X Window System applications as a client and server.

I'm running A/UX on a Macintosh IIfx with 8MB RAM on a Hammer 330MB drive (formatted with La Cie's Silverlining).

Also, is there anything I can do other than increase the memory or select "faster bitmap graphics" for the MacX performance benchmarks?

This article has been archived and is no longer updated by Apple.
First, make sure that you are running the current release of "X Window System for A/UX". It includes "MacX for A/UX" and "Native X11 Window System for A/UX". This software comes standard with A/UX 3.0. Here are some notes about these two products:

For "MacX for A/UX", the display server and the included "xcalc" client application are based on X11R3.

For "Native X11 Window System for A/UX", the display server and the "xstdcmap" client application are based on X11R4. The Xlib, the Xtoolkit, and other client applications are based on X11R3.

Because the Native X11 server for A/UX is based on X11R4, the performance behavior on the display server should be much improved over the X11R3 server.

To run X Window System with A/UX efficiently, some kernel parameters need to be adjusted, because of the number of processes and amount of memory space required by both the display server and client applications in a network environment.

Use the command "kconfig -av" to display the current kernel parameters, and adjust these parameters, if necessary:

NBUF
NFILE
NINODE
NPROC
MAXUP
NMBUFS

For an A/UX with 8MB RAM, the suggested values for these parameters are:

NBUF=1000
NINODE=600
NFILE=400
NPROC=100
MAXUP=100
NMBUFS=1000

NMBUFS is allocated buffers for the network. You can adjust them, if necessary. The above can be done via the "kconfig -n /unix" command. Then use "sync;sync;sync;reboot" to effect the change.

For MacX, other than increasing the memory size of the MacX application (default is 1500K), we are not aware any other way to improve the performance. The suggested memory size of MacX is 2500K. Use "Get Info" to change the size under A/UX Finder.

If physical memory is your concern, you can use the "TBMEMORY" environment variable to increase your virtual memory under A/UX. For instance, to make a 16MB virtual memory, put these two lines in your .profile file, then logout and login to effect the change:

TBMEMORY=16m
export TBMEMORY

Pascal: Speeding up Pascal text file reading (1 of 3)

This article has been archived and is no longer updated by Apple.
Although the READLN statement reads Pascal text files--for example:

```
READLN (FILEID, STRINGVARIABLE);
```

--this operation can be made much faster by using the routines contained in the following program. Three procedures do the work. Their operation is explained, line-by-line, below:

```
PROCEDURE FILLBUFFER;
(* Fills the working buffer with data
from the .TEXT file. *)
BEGIN
EMPTY := BLOCKREAD (INFILE,BUFFER,2) = 0;
(* Reads 2 blocks of the file into
BUFFER and leaves the variable EMPTY
equal to zero if the end of file
marker is not yet reached.*)
IF NOT EMPTY THEN BEGIN
(* If there is still unprocessed data
in the buffer, do this:*)
NOTNULLS := BUFSIZE +
SCAN (- BUFSIZE, <> CHR(0), BUFFER [1023]);
(* The length of a Pascal .TEXT file
should always be in multiples of 2
blocks. Since strings (lines) do not
span blocks, each block is likely to
contain nulls (ASCII ZERO) at the end.
This line returns the number of real
characters in the file, and discards
the null ones. *)
BUFINDEX := 0;
(* The working index into the buffer is
reset to zero after refilling the
buffer. *)
END;
END;

PROCEDURE OPENFILE (FNAME: STRING);
(* Opens the file using the name passed
by calling procedure.*)
BEGIN
IF ((POS('.text',FNAME) = 0) AND
(POS('.TEXT',FNAME) = 0)) THEN
FNAME := CONCAT (FNAME,'.TEXT');
(* Adds the .TEXT suffix if it's not
already there. *)

RESET (INFILE, FNAME);
(* Actually opens the referenced file. *)

FILLBUFFER; FILLBUFFER;
(* The first call to FILLBUFFER skips
over the 2 blocks of header
information on .TEXT files. The
second call actually fills the buffer
with information which will be used.*)
END;

PROCEDURE READFILE (VAR LINE: STRING);

(* Reads from the file and returns a string at a time in the variable LINE. A
```

word about the Pascal .TEXT file format: Lines are stored as ASCII
characters terminated with carriage returns. If a line contains any leading
spaces, and most Pascal source files contain some, these spaces are "packed"
into two bytes. The first byte is an ASCII DLE (decimal 16) signifying that
the line is packed. The second byte is a count of spaces to be expanded.
The Editor unpacks these lines automatically, as does a READLN from a file.
We do that operation ourselves in this procedure. The increase in speed is
because we are using highly specialized routine, whereas the READLN
intrinsic is very general in nature, accepting strings, integers and reals
from the keyboard as well as from files. Note that this format is optimized
for Pascal source files and it wastes two bytes for each and every line that
does not contain leading spaces. *)

VAR INDENT, LINELEN: INTEGER; (* INDENT is the number of
space characters to add.
LINELEN is the length of the
new string to be formed. *)

Apple SuperDrive and 800K Disk Drive Compatibility

I have a Macintosh II with an 800K floppy drive. I want to upgrade to an Apple SuperDrive (formerly Apple FDHD). Can I still use the 800K drive and have a system with two floppy drives?

This article has been archived and is no longer updated by Apple.
When upgrading a Macintosh II system to include a SuperDrive, new ROMs (Macintosh IIx ROMs) and a SWIM chip (replaces the IWM) are installed. The 800K disk drive from the Macintosh II is supported and will continue to work as before. For more information, search under "Macintosh II 800K Drive".

LaserWriter and LaserWriter II: How to Minimize Smudging

I am seeing a lot of smudging with the LaserWriter and LaserWriter II printers in our office. What's wrong? What can I do to minimize this?

This article has been archived and is no longer updated by Apple.
In most cases, smudging is due to the operation of the printer below the stated minimum 20 percent relative humidity. This often occurs in the winter when dry, cool air is brought inside and warmed up. Because of the latent humidity in the printer, paper, and toner cartridge, it takes approximately 24 hours for a change in humidity to reflect in the results. The condition of the printer, paper, and toner can all have a significant impact on the print quality. Changing parts or modules has no effect on a humidity-related problem.

Here are some suggestions for minimizing smudging:

* Use a humidifier in the vicinity of the printer and its paper. Try to maintain the humidity at a level of 40 to 70 percent.

* Place a moist sponge with the paper supply in a closed container (like sealed cabinet.) This does not control the humidity level within the printer or toner. This method, therefore, has limited effectiveness.

* Before inserting paper into the paper cassette, use a static-dissipating spray (e.g., Static Guard¬.)

* Clean the printer regularly to reduce toner deposits in accordance with the "Owner's Guide" recommendations.

In conclusion, the best solution is to operate the printer within its specified humidity range.

Using Shiva NetSerials to Manage Shared Serial Ports

I have a decent-sized AppleTalk network (40 workstations, two servers, bridge, and so on). I need to add about 10 share-able serial ports to bridge into an existing Wang system. Ideally, I'd like to find some device like a com-port server, something with up to ten ports, that would manage the allocation of the ports. I have considered using ten Shiva NetSerials, but I don't like the "trial and error" method of finding an available NetSerial. Does anyone make a device like this?

This article has been archived and is no longer updated by Apple.

From your description it sounds as if you want a network communication "hunt group"-like service, that will automatically hunt for the next available communication server when the first communication server is busy. You can do this now with the Shiva NetSerials.

Just choose all of NetSerials you want in your "hunt group" through the Chooser and your call will be routed through whichever NetSerial is available. Because the NetSerial is an independent (after initial configuration) network device, you won't need to dedicate a computer to manage it.

For more details, search the Technical Info library under "Shiva."

DBF Files: Accessing from Macintosh

Several people in my department are interested in using their dBASEIII+ or Clipper data files in the normal DBF file format by both MS-DOS users and Macintosh users. I'm thinking of solutions like FoxBASE+/Mac, dBFast/Mac, or 4th Dimension with dB_Interface from CT-DATA.

Could you summarize all the possible solutions that we could implement? Some of these people are looking for solutions with the DBF files on a file server somewhere in the network. Others just want to take the DBF files and transfer them from a PC to a Macintosh. One of them is specifically interested in a HyperCard solution.

Are there any HyperCard externals available that make direct access to DBF files possible? Is there a similar feature like the dB_Interface with 4th Dimension, for Omnis 5 from Blyth Software?

This article has been archived and is no longer updated by Apple.
We have a number of suggestions on how to access DBF files from a Macintosh.

The first solution is, as you mentioned, FoxBASE+/Mac. FoxBASE+/Mac Multi-User works together FoxBASE+/LAN to allow concurrent operation on a network that supports both MS-DOS and Macintosh users. Data on the network is available to both machines at the same time, and access and manipulation operations are done identically. If you want to transfer DBF files from a DOS machine to a Macintosh, conversion is required. The index files for FoxBASE+/Mac are different, however. The first time you use an index in FoxBASE+/Mac on a DBF file from a DOS machine, a new index file will be created.

HyperCard can also be used as a front end to DBF files. Nittany Development Group has a product called DBF-Access Tools for HyperCard. This is a set of XCMDs for HyperCard used to import and export data in a variety of different ways to and from DBF files. This is not multi-user, nor does it update any of the DBF index files. If data was exported from HyperCard to the DBF file, and you wanted to use dBASEIII PLUS with this DBF file again, you would need to reindex the database. Using DBF-Access Tools for HyperCard, the data in a DBF file could easily be read into HyperCard and manipulated.

Another HyperCard approach is a product called DashBoard from Symmetry. With DashBoard you can again read and write to DBF files. It updates the indexes of dBASE III files. Other applications, like FoxBASE or Clipper, will not have their indexes updated. This product is currently in beta form.

4th Dimension can access DBF files by using dBinterface Rapid from CTDATA. This is a set of externals for 4th Dimension that does high-speed, data conversion. Use it to move data between DBF files and 4th Dimension and the dBASE format. CTDATA also has a product called dBinterface Interactive. This gives you index support for DBF files and record-by-record access. It supports shared access via any AFP-compatible network, though the dBASE-compatible database must support multi-user access.

DbFast/Mac from Bumblebee Software will also read DBF files. This is a dBASE language development environment. It is a single-user database.

Finally, you can use Omnis 5 from Blyth Software. Omnis can import and export data from DBF files. The DBF files cannot be accessed by more than one user at a time, though. You can create a transaction where you import data, manipulate it, and then export the data back out to the DBF file. When exporting data from Omnis to the DBF files, the indexes are not updated.

People looking for multi-user solutions using DOS machines and Macintoshes at

the same time should look into FoxBASE+/Mac and 4th Dimension using dB_Interface from CTDATA. Converting data from DBF files on a DOS machine to a Macintosh is much easier, and you have quite a few options to choose from. The deciding point seems to be what application you want to run on the Macintosh.

80MB Hard Drive: External to Internal Conversion

My 80MB external hard drive worked fine upon arrival. However, after I took it out of its case and made it an internal drive, it won't boot.

This article has been archived and is no longer updated by Apple.
The modified drive is probably not terminated automatically. To see if this is the problem, put a SCSI system cable with a SCSI Terminator on the external SCSI port. If it boots with the external terminator, then you need to have the jumpers on the bottom of the drive set to terminate it. Contact your authorized Apple service provider for this.

A/UX: How to Share a LaserWriter with an Apollo Workstation

I have a Macintosh II, Apollo workstation (with Interleaf), and a LaserWriter. What do I need to print Apollo files on the printer?

Also, what can you tell me about Information Presentation Technologies' UShare software for networking Macintoshes and Apollos?

This article has been archived and is no longer updated by Apple.

One way to print Apollo files is to transfer the files to the Macintosh and then print from the Macintosh. To transfer files, make a direct, serial connection and then use Kermit or EtherNet and NCSA Telnet. The transferred files could then be printed.

UShare makes an AppleTalk board for the Apollo. With this board and Apollo host software, the Apollo becomes a host. Add print server software and you can spool files. You need the AppleTalk board for Apollo, UShare host software, and UShare print-server software. There is also an option for a mail program, if you need it.

Pascal: Speeding up Pascal text file reading (2 of 3)

This article has been archived and is no longer updated by Apple.

```
BEGIN
IF BUFINDEX >= NOTNULLS THEN FILLBUFFER;
(* If the buffer needs refilling,
go and get another buffer. *)
IF NOT EMPTY THEN BEGIN (* If the file is not yet empty,
then do the following: *)
LINELEN := SCAN (BUFSIZE, = CHR(13), BUFFER [BUFINDEX]);
(* Set LINELEN to the number of
characters from the current
buffer pointer position
(BUFINDEX) to the next carriage
return in the buffer.*)
IF BUFFER [BUFINDEX] = CHR (16) THEN BEGIN
(* If the character at the buffer
index is an ASCII DLE, then we
have to unpack the leading
spaces. *)
INDENT := ORD (BUFFER [BUFINDEX + 1]) - 32;
(* Set INDENT to the number found
at BUFINDEX + 1, the number
of space characters to
insert. *)
(*$R-*)
LINE [0] := CHR (LINELEN + INDENT - 2);
(*$R+*) (* Turn off Range Checking so we can
manually change the string length. Set
the length of LINE to the number we had
already gotten plus the number of spaces
to unpack, throwing away two bytes for
the DLE and count bytes. Turn Range
Checking back on.*)
IF INDENT > 0 THEN FILLCHAR (LINE [1], INDENT, ' ');
(* If there are spaces, then fill in the
appropriate number of them, starting
with the first position in the new
string. *)
IF LINELEN > 2 THEN MOVELEFT (BUFFER [BUFINDEX + 2],
LINE [1 + INDENT], LINELEN - 2);
(* If the string is more than 2
characters long, then move the rest of
it from the buffer into the string
starting just after the leading spaces
previously inserted. *)
END ELSE BEGIN
(* No DLE character was found. That
means straight ASCII. *)
(*$R-*)
LINE [0] := CHR (LINELEN);
(*$R+*)
(* Turn Range Checking off, set the
length of the string to LINELEN, and
turn Range Checking back on. *)
IF LINELEN > 0 THEN MOVELEFT (BUFFER [BUFINDEX],
LINE [1], LINELEN);
(* Move the characters from the buffer
into LINE as above. *)
END;
BUFINDEX := BUFINDEX + LINELEN + 1;
(* Sets the pointer to the first
character of the next string in the
buffer for the next time through. *)
```

```
END;
END;
```

Here's a program that demonstrates the difference in speed between the two methods of reading strings:

```
PROGRAM QUICKREAD; (* Very fast line read routine *)
CONST BUFSIZE = 1024;
BUFLEN = 1023;
FILENAME = 'QWERTY9.TEXT';
(* Probably not on user disk *)
VAR LINE: STRING;
INFILE: FILE;
TEXTFILE: TEXT;
CH, OPTION: CHAR;
EMPTY, HELL_FREEZES_OVER: BOOLEAN;
ERROR: INTEGER;
NOTNULLS: 0..BUFSIZE;
(* # of non-null chars *)
BUFINDEX: 0..BUFSIZE;
(* Index within buffer *)
BUFFER: PACKED ARRAY [0..BUFLEN] of CHAR;
```

A/UX: How to List Remotely-Mounted Directories (8/94)

How can I find out which directories are remotely mounted?

This article has been archived and is no longer updated by Apple.
By using the "-d" option with the /usr/etc/showmount command, you can get a list of the directories that are remotely mounted on other systems on the network. It does not list the system hostnames, just the directories.

Example output from the command line "showmount -d":

/
/users
/usr
/usr/catman

A/UX: How to Avoid Timeouts on an NFS Server

Heavy usage of the NFS server creates an NFS timeout. It happens, for example, when a heavy compilation is ocurring on the server. Is there any way to avoid this?

This article has been archived and is no longer updated by Apple.
Try increasing the timeo variable for NFS when the NFS systems are mounted at startup.

Published Date: Feb 18, 2012

A/UX: How to Make an NFS File System Mount Automatically (9/94)

My NFS file systems aren't mounting automatically.

This article has been archived and is no longer updated by Apple.
Usually, one of two things cause this. The first is that the NFS entry in /etc/fstab is incorrect. To check this, follow these steps:

1) Log on as "root".

2) Edit the file /etc/fstab. This file lists all of the partitions which should be automatically mounted when the system is booted into multi-user mode.

3) As needed, add an entry for each NFS partition that you would like mounted automatically. The format needed is displayed in /etc/fstab:

rhost_1:/filename /mnt ignore rw 0 0

rhost_1 is the name of the repote host. "filename" is the file system to be mounted. /mnt is the mount point, the directory to which the file system will be attached.

The other reason is that NFS file systems are mounted at startup only if the appropriate line has been altered in /etc/inittab. To see if yours is correct, follow these steps:

1) Log on as "root".

2) Enter the command:

grep mount /etc/inittab

You should see:

nfs8:2:once:/etc/mount -at nfs > /dev/syscon 2>&1

If this is not displayed, do these steps:

1) Edit the file /etc/inittab

2) Change the line

nfs8:2:off:/etc/mount -at nfs > /dev/syscon 2>&1

to

nfs8:2:once:/etc/mount -at nfs > /dev/syscon 2>&1

3) Save the file and quit the editor.

4) Shut the system down into single-user mode.

5) Bring the system back up into multi-user mode. The system will display the names of the local and NFS partitions as they are mounted.

The other reason that this happens is because you are in single-user mode. To find your run level, type

who -r

This should be displayed:

run-level 2 Apr 14 09:59 2 0 S

The number in the second column of the output should be a "2".

If it is an "S", your system is in single-user mode and must be booted into multi-user mode. To boot into multi-user mode:

1) Enter the command:

init 2

This will start the system booting into multi-user mode. During the booting process, it will ask if you'd like "the rest of the partitions" checked by fsck.

2) Press "Y" and Return.

When the system is up in multi-user mode:

1) Log on as "root".

2) Enter the command: df

The output will list all currently-mounted partitions, both local and remote.

A/UX: Reasons Why NFS File Systems Don‘t Mount (9/94)

My /etc/inittab, /etc/fstab are configured correctly, and I'm in multi-user mode, but my NFS file systems still don't mount.

This article has been archived and is no longer updated by Apple.
There are two common reasons for this. The first is that the file /usr/etc/rpc.mountd is missing or corrupted. To check, enter the line:

ls /usr/etc/rpc.mountd

It should display:

/usr/etc/rpc.mountd

If it doesn't, the file /usr/etc/rpc.mountd must be restored from your backups or the A/UX CD-ROM.

A second reason is an incorrect entry in /etc/servers. To check this,

1) Log on as "root".

2) Enter the line:

grep mount /etc/servers

You should see:

rpc udp /usr/etc/rpc.mountd 100005 1

If you don't, follow these steps:

1) Edit the file /etc/servers by adding this line:

rpc udp /usr/etc/rpc.mountd 100005 1

2) Save the file and exit the editor.

3) Shut the system down into single-user mode.

4) Boot into multi-user mode. The names of the local and NFS partitions appear as they are mounted.

A/UX: Solution to "RPC_MAP_FAILURE" Error

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I tried to mount a remote file system and got the error:

mount: <hostname> server not responding: RPC_MAP_FAILURE

This article has been archived and is no longer updated by Apple.
There are four, common reasons for this. First, check that you do not have an incomplete or marginal Ethernet connection. Follow these steps:

1) Are cables correctly seated on connectors?

2) Are cable in good condition physically? There should not be crimps or bends in the cable.

3) Check that all cables attached; make sure that none has been accidently disconnected.

A second reason is that the remote host from which you are mounting a file partition may be down. Check with the administrator of the system. You will not be able to mount any file system from that system until the remote host is up and running.

A third reason is that the /etc/portmap daemon may not be running. Check this by following these steps:

1) Enter the line:

ps -ef | grep portmap

The output displayed should look like this:

root 90 1 0 Apr 25 ? 0:04 /etc/portmap

The numbers in the output may differ on your system. If you do not receive this output, do these steps:

1) Log onto the system as "root".

2) Enter the line:

grep portmap /etc/inittab

The output should look like this:

nfs0:2:wait:/etc/portmap

If it doesn't, edit the file /etc/inittab and modify it to look this way.

3) Shut the system down into single-user mode; run-level S.

4) Reboot the system into multi-user mode; run-level 2.

A fourth reason is that the /etc/portmap daemon on the remote host isn't running. To check this, follow these steps:

1) Log onto the system as "root".

2) Enter the command

rpcinfo -p

followed by a space and the name of the hostname you wish to check. You should get a list of registered program numbers. If you don't:

3) Shut the system down into single-user mode; run-level S.

4) Bring the system back up into multi-user mode; run-level 2.

PLI‘s CD-ROM Drive Works with Macintosh and PCs

Do you know of a CD-ROM drive that can connect to both a stand-alone PC and Macintosh?

This article has been archived and is no longer updated by Apple.
Although computer-oriented CD-ROM periodicals list many such solutions, we haven't had ready access to most of them. We have tested the PLI CD-ROM drive and it worked as advertised:

"The PLI CD-ROM Drive is both compatible with the Macintosh and PCs; it reads CD-ROMs in all standard formats and plays audio CDs too. Headphone, analog, and digital audio output as well as external termination and SCSI ID switching are standard."

Check with computer dealers near you and read appropriate magazines for other products.

Macintosh IIsi/LC: Sound CDEV Problem and Fix

If I open the Control Panel and select the Sound CDEV, then move the Control Panel window to the edge of the screen (either left or right), then click the "Add..." button to record a sound, the modal dialog window that opens is almost entirely off the screen. Because I'm unable to click a button to make this dialog go away, I'm stuck.

This article has been archived and is no longer updated by Apple.
There is a problem with the Sound CDEV. The only configurations affected are:

Macintosh LC or Macintosh IIsi, running System 6.0.7 and MultiFinder (there is no problem under Finder).

Press Command-Period and you will return to the sound CDEV.

TA45051_Texas_Instruments_Emulates_VT_VT_VT_(TIL06535).pdf

Texas Instruments 928 Emulates VT320, VT220, VT52

For a Macintosh user, is there a substitute for the Texas Instruments TI928 terminal?

This article has been archived and is no longer updated by Apple.
The Texas Instruments TI928 terminal emulates VT320, VT220, and VT52 terminal types. It has RS-232-C and RS-423 capability and includes a printer port for a direct-connect printer.

Any Macintosh terminal emulation package capable of supporting the above terminal types should be a viable substitute for this terminal.

Internet Router & 6.0.7: "Coprocessor not installed" error

I'm having a problem with System Software 6.0.7 and the AppleTalk Internet Router software 2.0. When installed on a Macintosh IIsi with a NuBus Adapter and a TokenTalk card (TokenTalk version 2.0 Arose Prep version 1.1) I receive a system error "Coprocessor not installed". When I install the Internet Router software on a Macintosh IIcx, the system does not recognize the router software.

This article has been archived and is no longer updated by Apple.
We tested the same configuration on a Macintosh IIsi acting as a router, and had no trouble installing or running the software.

We've heard complaints about the "Coprocessor not installed" message in varied situations with several different applications. Please see an article titled "Macintosh System Software 6.0.7: Troubleshooting (1 of 3) for more information on this error.

If you can't get the router software to run on the Macintosh IIcx, there may be a problem with the way you're installing or configuring it. We recommend you start the installation from scratch using the correct system installer disks to install System software, and the Apple Networks Product installer disk to install the network drivers and the router software. The router should load successfully after re-installation in a clean system.

Apple‘s Disability Resources (5/97)

What resources does Apple offer for individuals with disabilities, rehabilitation professionals, and special education teachers?

This article has been archived and is no longer updated by Apple.

This article describes Apple's disability-related information resources (managed by Apple's Worldwide Disability Solutions Group), as well as related assistive technology organizations.

Apple Computers Disability Resources

==========

Since 1985, when we created the industry's first Disability Solutions Group, Apple Computer has been at the forefront of making computer technology that meets the special needs of children and adults with disabilities around the globe. It is our belief that computers do not just make people more productive, but that they have an almost magical way of increasing an individual's independence. Self-expression. Participation. Choices. And self-esteem.

That's why our goal is, just as it was 10 years ago, to change the experience of disability in positive, constructive, and--where appropriate--dramatic ways.

Toward that end, we pay special attention to the design of our own products to ensure that they are fully accessible to individuals with disabilities. And we work with numerous Macintosh developers who offer a rich selection of add-on accessibility products for our computers.

Apple provides a series of disability-related information resources that are available to you. Chief among them is an information packet containing a comprehensive database of access products called the Mac Access Passport (MAP). This information is available free-of-charge by calling 800-600-7808 (voice), or 800-755-0601 (TTY).

Four short videotapes are also available through Apple's StartingLine; catalog at 800-825-2145 ($8/ea.; please refer to the Part# when ordering). The videotapes are:

Access

See how the lives of four people with disability have been transformed by Apple technology. 10 min. Part#APL829.

Chapter One

Explore ways that future technologies might enable people with disabilities. 10 min. Part#APL830.

Curb Cuts

Television personality Harry Anderson shows you what makes Macintosh the most accessible computer. 8 min. Part#APL831.

Independence Day

See how the Macintosh helps individuals with physical and learning disabilities improve the quality of their daily lives. 10 min. Part#APL832.

Finally, to receive printed information about Apple products and services, we encourage you to use our toll-free, automated fax system, AppleFAX, by calling 800-462-4396. The service is available 24 hours a day, 7 days a week (you must have a fax machine to use this service).

If you have any questions, comments, or thoughts that you would like to bring to our attention, you can contact us at any time at the following address:

Apple Computer, Inc.

One Infinite Loop, M/S 38-DS

Cupertino, CA 95014

800-600-7808 - voice

800-755-0601 - TTY

Apple's Disability Resources Online

==========

Imagine a place where the post office never closes. Where the library contains vast amounts of information-all at your fingertips. A place where discussions--small and large--are held around the clock. A place in which to hang out with old friends... and to make new ones. Imagine a place without boundaries. Imagine a place without tired stereotypes.

Apple Computer participates on several online information services in order to disseminate information and promote discussion about Macintosh assistive technology. While every online service has its own character and approach to disability content, one thing is consistent among the services listed below: they all offer the most current information from Apple Computer about Macintosh disability solutions.

Internet

Apple Computer's site on the World Wide Web is one of the most popular areas on the Internet. Available resources include information about all of Apple products and services, technical support, and extensive Macintosh and Newton software libraries. The central Apple Web site also contains information about Macintosh disability solutions, including the most uptodate version of the Macintosh Disability Resources database.

Path: To reach the main Apple Home Page, point your Web browser to:

http://www.apple.com or http://www.info.apple.com.

To reach Apple Computer's Disability Solutions home page, point directly to:

http://www.apple.com/disability/welcome.html.

For more information about Apple's presence on the Internet, email:

webmaster@apple.com

Other Online Services

In addition to the services listed above, Apple Computer occasionally distributes important information about Macintosh assistive technology on a variety of other online forums, including: America Online (disAbilities forum); Internet Newsgroups (misc.handicap and alt.education.disabled); CompuServe (Disabilities+ forum); Prodigy (Health forum); and GTE's SpecialNet (assistive.devices bulletin board).

Assistive Technology Resources

==========

We highly recommend that you contact the following organizations for additional information about technology for individuals with disability.

Alliance for Technology Access

2173 East Francisco Blvd., Ste. L

San Rafael, CA 94901

415-455-4575

The Alliance for Technology Access is a national network of non-profit resource centers that provide information and consultation about computer use by children and adults with disabilities.

Closing the Gap

P.O. Box 68

Henderson, MN 56044

612-248-3294

Closing the Gap publishes a bi-monthly newsletter and conducts an annual conference each October focusing on the use of computer technology by and for individuals with special needs.

HEATH Resource Center

1 Dupont Cir., NW, Ste. 800

Washington, DC 20036

800-544-3284

The HEATH Resource Center is a national clearinghouse for information about assistive technology, offering material to consumers, organizations, and universities.

Trace R&D Center

S-151 Waisman Center

1500 Highland Ave.

Madison, WI 52705

608-262-6966

The Trace R&D Center is a leading research and development site specializing in rehabilitation engineering and assistive technology tools. Trace publishes a comprehensive resource book of accessibility products.

Chooser: Zone List Time-Out Values

I have 53 zones on the Northern Telecom Internet. It appears that the Chooser zone list display times out after approximately 40 zones have been displayed, when a single user is connected to the network at 2400 baud. (This timeout doesn't occur at 19,200 baud.) The site has a pair of Shiva TeleBridges and a pair of Hayes V Series 9600 V.42 modems on the network.

Can we use ResEdit to modify the Chooser's zone list time-out values?

This article has been archived and is no longer updated by Apple.
Here is some information about the Chooser that may be of help.

When the Macintosh Chooser is opened, several things happen.

The Macintosh first sends a ZIP GetZoneList request to whatever AppleTalk router it has stored as its "A-ROUTER" value (the last router this Macintosh received an RTMP packet from).

The GetZoneList command is sent to the router with the zone list index set to 1. This tells the router to return the zone list to the requesting workstation, starting with the first entry.

The ZIP GetZoneList command is sent using the ATP at-least-once (ALO) protocol.

The time-out value used for the ATP request is set to 1 second; the number of retries for this transaction is set to 5.

The Macintosh sends out the GetZoneList command and expects to hear back from a router within one second. This is reasonable, because the router is usually connected directly to the same cable that the requesting Macintosh is attached to.

The router replies to the GetZoneList command by sending a ZIP GetZoneList reply with the current zone list. If the zone list does not fit in one ZIP reply packet, the router indicates that there are more zones by setting a flag in the reply packet. The Macintosh requesting the zone list would then send another GetZoneList request to the router with the zone list index set to the number of the last zone name in the current reply packet plus one. This tells the router to then send the next chunk of zone names starting at index number X. A ZIP GetZoneList reply packet can usually hold around 40 zone names, but the exact number of zone names you will get into a single ZIP reply packet varies, depending on the length of the zone names themselves.

This may offer an explanation to why you have seen the symptoms you described.

The user opens the Chooser:

ZIP GetZoneList(index=1) -----> router
wait 1 second
re-transmit 2nd attempt
ZIP GetZoneList(index=1) -----> router
wait 1 second
re-transmit 3rd attempt
ZIP GetZoneList(index=1) -----> router
wait 1 second
re-transmit 4th attempt
ZIP GetZoneList(index=1) -----> router
wait 1 second
re-transmit 5th and last attempt
ZIP GetZoneList(index=1) -----> router

<----- router responds with a GetZoneList()
with the more to come flag set.

ZIP GetZoneList(index=40) -----> router
wait 1 second
no response
ZIP GetZoneList(index=40) -----> router
wait 1 second
no response
ZIP GetZoneList(index=40) -----> router
wait 1 second
no response
ZIP GetZoneList(index=40) -----> router
wait 1 second
no response
ZIP GetZoneList(index=40) -----> router
wait 1 second
no response

No response, so we give up and display the zones we've received so far in the Chooser. The user ends up seeing only 39 zones.

In summary, if the router does not respond back to the first GetZoneList request within one second, we re-send the request. If, at the end of five requests, we still haven't received a reply, we give up and display no zone list in the Chooser window. If we receive the initial zone list, and the router has marked the "more to come" flag, we will request the next set of zone names with the same time-out and retry values as used previously (1 and 5). This is how you can end up with partial zone lists.

There is no easy way to change the retry or time-out values associated with this ZIP transaction. The AppleTalk protocol suite was developed to be used on a local area network where high reliability and low round-trip delays are prevalent. Apple has no plans to change or adopt the protocol to suit every physical data link on which AppleTalk may be implemented. Several third-party companies have developed products that push the AppleTalk protocol to its limits when used with their asynchronous or wide-area network products.

A/UX: The "network unreachable" Remote Mount Error (8/94)

I tried to mount a remote file system and got the error:

network unreachable

This article has been archived and is no longer updated by Apple.
This could be because the Ethernet card or cable connection is not working correctly. Here are four troubleshooting steps:

1) Make sure that the Ethernet cable from the Ethernet card to the rest of the network is connected and seated properly and snugly.

2) Check that there is not a broken connection in the main network cable itself.

3) Check that cables do not show any physical signs of damage. Ethernet cables should not be crimped, bent, or squished.

4) Replaced all cables that show excessive wear.

A/UX: How to Avoid VAX-to-Macintosh File Transfer Problems

Article Change History

08/31/92 - REVIEWED
*For technical accuracy

I transferred some files as text files from a VAX to a Macintosh using Kermit.
About every 10 files, I see garbage.

This article has been archived and is no longer updated by Apple.
The best way to do the transfer is to set the file type on both systems as
binary, not as text. It works with no problem that way.

Published Date: Feb 18, 2012

A/UX: Diagnostics for a "ping" Error

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

After executing ping on a remote Sun system, I got the error

ping:send to: network is down

and was logged off. I had all correct daemons running. When I run ruptime, it shows no systems up.

This article has been archived and is no longer updated by Apple.
Assuming that the systems were indeed up and running, do these diagnostic steps:

1) Reboot the system.

2) Check that cabling is correct.

3) Try another system to see if other systems can be seen.

4) Check that terminating resistors are in place.

5) Try reseating the Ethernet board. If that doesn't work, try a new board.

6) Check your IP address to see if it's valid.

7) Also, check your domain name.

A/UX: Telnet and "ftp in" Problem Solved

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

I have a Macintosh IIx and an EtherTalk board. Telnet and "ftp out" work fine. Telnet and "ftp in" cause the following messages on the screen:

ae0: overflow NIC reset failed
ae6_intr: receive overflow warning

This article has been archived and is no longer updated by Apple.
Don't worry about it. It appears only on very high-traffic networks and won't crash the system. You can reduce the frequency of messages by doing some network tuning. If you want, you can increase the number of NMBUFS in the kernel with

kconfig -n /unix.

You can list your kernel parameters with

kconfig -avn /unix.

--- WARNING ---

Whenever changing kernel parameters, be sure to save a known-good working /unix file to another name. You can then use this kernel as a backup in case you create a non-functioning kernel.

Two Mirrored Backup Products

Is there a mirrored backup capability for the Macintosh in the Reflections software from Profyle Computers, Ltd in Oxon, England.

This article has been archived and is no longer updated by Apple.
Yes. For contact information, see the listing under "Profyle" in the Technical Info library. A similar type of backup utility was recently announced. Natural Intelligence publishes a product called Shadow that does automatic backup. They state that:

Shadow periodically copies the documents that have changed since they were last backed up. Shadow can backup onto any floppy disk, hard disk, removable disk, network server, or Finder-mountable tape drive.

Also, Golden Triangle has DiskTwin, a fault-tolerant, disk storage device for Macintosh II family computers. Golden Triangle states:

"DiskTwin is a Macintosh software package, facilitated by a proprietary NuBus add-in card, that automatically and transparently uses a second SCSI bus to make a real time copy of the contents of a primary hard drive onto a secondary hard drive. Technically, this operation is known as disk duplexing."

To the question "What is disk duplexing?", Golden Triangle responds:

"Disk duplexing is a technology today widely used in the mainframe and minicomputer world and in large microcomputer networks to ensure continuous operation. It is vital where end users simply cannot afford to lose any data or afford for a system to be down any amount of time. Now Golden Triangle uses proprietary software and hardware to bring this technology within economic reach of even a single Macintosh user."

Golden Triangle answers "How does DiskTwin work?" as follows:

"Drop the DiskTwin control panel device (CDEV) into your System Folder. Place the DiskTwin NuBus card into your Macintosh II. Attach a drive of the same kind as your primary disk onto the DiskTwin card. For example, if you have an Apple Quantum 80 internal, connect an Apple Quantum 80 external to the DiskTwin card. Restart your computer, and select the drive you want to twin. The twin is invisible to the Macintosh DeskTop, so it can't be used accidentally. When you do need it, you can immediately mount the twin onto the DeskTop from the DiskTwin CDEV. You won't even notice DiskTwin is working, so you can forget about it.

"But DiskTwin doesn't forget about you. DiskTwin runs continuously, creating a twin of your primary disk as often as you save to disk. Unlike software-only mirroring solutions, DiskTwin won't slow your system to a crawl. When your hard disk fails, mount the twin and you're back in business. Should the Macintosh SCSI hardware fail, your DiskTwin SCSI port remains operational."

HyperCard: Dragging Over Text with Command Key Down

In HyperCard, when I hold down the command key while the pointer is over a text field (it doesn't matter whether the field is locked), the pointer changes from an insertion point to a hand. If I then drag this hand pointer over the field (still holding down the command key), up to one entire line of text is immediately copied into the message box. What is this feature called and what is it for?

This article has been archived and is no longer updated by Apple.
This feature has been a part of HyperCard for some time, but is not documented. Here's one way to take advantage of it:

You can write a handler that builds a find command in the message box, then "types" return to execute the command. For example, here's a handler that finds the next occurrence of whatever text has just been copied into the message box:

```
on mouseUp
put "find whole"&&quote&message&quote into message
repeat 2
-- The first find will be the text you just copied into the message box;
-- the second find will be the next one, if any.
type return
end repeat
end mouseUp
```

Each time you then press the return key (without changing the content of the message box), you'll go to the next occurrence of the same search string.

HyperCard 2.0: Bypassing Dialog Boxes

When I use certain HyperCard 2.0 commands, either from the menu bar or from a script, I get a dialog box that must be responded to. Examples:

command	dialog box
Import Paint...	Import Paint from...
Export Paint...	Save Paint document as:

Is it possible to execute these commands from scripts, or from the message box, without having to respond to the dialog boxes? And is it possible to open a stack in new window from a HyperTalk script, also without dealing with a dialog box?

This article has been archived and is no longer updated by Apple.
Here are some commands that do what you want. In the examples, "stackname" represents either a stack name, or the path to a given stack.

The first one imports a bitmap from the specified MacPaint file to the card picture. It starts with the top-left corner of the MacPaint file, and clips to HyperCard's current card size. It requires that one of HyperCard's paint tools (such as the line tool) is first chosen.

```
choose line tool
import paint from file "stackname"
```

The next one creates a new MacPaint file, to which it exports the card image. This is the equivalent of doing a screen dump from HyperCard, but you get to choose the name of the output file in advance.

```
choose line tool
export paint to file "stackname"
```

Here's a command that opens a specified stack in a new window:

```
go "stackname" in new window
```

And one that creates a new stack and gives it a name:

```
create stack "stackname" <with backgroundname> <in new window>
```

The card size of the current stack becomes the card size of the new stack. If no background is specified, the new stack is created with a blank background. Otherwise, a copy of the specified background becomes the background of the new stack. If "new window" is specified, the new stack is created in a new window -- in other words, the old card window remains on-screen.

This one saves a copy of the specified stack under the new name you specify in advance:

```
save stack "stackname1" as "stackname2"
```

Pascal: Exponents

This article has been archived and is no longer updated by Apple.
The calculation 10 ^ X is not included in the UCSD Pascal definition. The system intrinsic PWROFTEN ("power of ten") returns 10 ^ X, provided X is an integer in the range 0..37. (Please refer to page 45 in the Pascal Language Reference manual.)

The function EXP (in the library unit TRANSCEN) is of the form e ^ X, where X is a real number. The relationship between 10 ^ X and e ^ X is:

10 ^ X = e ^ (X LN 10) (LN = natural log)

Here is a simple program which illustrates the use of Pascal exponents:

```
PROGRAM EXPONENT;

USES TRANSCEND;

BEGIN
WRITELN ('10 ^ 3 = ',PWROFTEN(3));
WRITELN ('e ^ 3 = ',EXP(3));
WRITELN ('10 ^ 3 by the conversion = ',EXP(3*LN(10)));
END.

A/UX: How to Copy Eschatology Partition

Article Change History

08/31/92 - REVIEWED
* For technical accuracy.

I need to copy an A/UX system from one drive to another, but I have a problem with the A/UX Eschatology partition. I set up the partitions on the new drive as on the first drive, except for some free space, which I have configured as usr space. I did a dd copy of the root partition.

I then hoped that by doing an eupdate I would be able to update the Eschatology partition. When I try this (I am able to boot from the new drive without any problem), I get messages about the inability to mount s3 and attempt to unmount slice 3. (I have not defined any slice 3.) Further messages refer to typewriter problems and the like.

What is the problem? Why is eupdate attempting to mount a slice that doesn't exist?

This article has been archived and is no longer updated by Apple.
From what you described above, you copied only the root file system. You did not copy the Eschatology partition to the new drive. To copy the Eschatology partition, do the following (assuming X is the source disk SCSI ID and Y is the target disk SCSI ID), and assign slice 3 for the Eschatology partition:

```
# pname -cX -s3 "Eschatology 1"
==> /dev/dsk/cXd0s3
# pname -cY -s3 "Eschatology 1"
==> /dev/dsk/cYd0s3
# dd if=/dev/dsk/cXd0s3 of=/dev/dsk/cYd0s3 bs=20k
# pname -u /dev/dsk/cXd0s3
# pname -u /dev/dsk/cYd0s3
```

Then, you can issue the "eupdate" command, which updates /unix and network files like /etc/HOSTNAME, /etc/NETADDRS, ... for Eschatology partition. Make sure that before doing "eupdate" that the Eschatology partition is not pnamed or mounted, because the "eu" program automatically does all the "pname", "pname -u", "mount", and "umount" on the Eschatology partition.

You might have got the error message from "eupdate", because the Eschatology partition was still pnamed or mounted. "umount" and "pname -u" the Eschatology partition and do "eupdate" again. Other similar error message like

Can't mount...:No space left on device

might occur if the Eschatology file system is almost full. In that case, remove some of the files like /mnt/unix from the Eschatology file system and do "eupdate" again.

To remove file(s) from the Eschatology partition, you have to "pname" and "mount" the Eschatology partition first. For example, to remove "unix" from Eschatology partition then "eupdate":

```
# pname -cY -s3 "Eschatology 1"
==> /dev/dsk/cYd0s3
# mount /dev/dsk/cYd0s3 /mnt
# rm /mnt/unix
# umount /dev/dsk/cYd0s3
# pname -u /dev/dsk/cYd0s3
```

A/UX 2.0 ftime() and open()

I am doing some A/UX 2.0 benchmarks and am having problems in two areas that involve C code. First, I need the equivalent of the ftime function on a Sun for timing execution time. The second is how to do a synchronous write to disk. The usual "write (o_sync)" command doesn't seem to be working.

This article has been archived and is no longer updated by Apple.

```
1) As far as we can tell, the ftime() function call that appears in most BSD
  UNIX systems (including Sun UNIX) is obsolete and now replaced by the
  gettimeofday() function call.  A/UX has gettimeofday() but not ftime().

  From the structure returned by ftime() and the new structures used by
  gettimeofday(), it should not be difficult to use the new gettimeofday()
  instead of the obsoleted ftime().  The structure returned by ftime() is
  defined in <sys/timeb.h> of BSD UNIX as:

          struct  timeb
          {
               time_t          time;
               unsigned short  millitm;
               short           timezone;
               short           dstflag;
          };

The structures used by gettimeofday() are defined in <sys/time.h> as:

          struct timeval {
               long    tv_sec;     /* seconds since Jan. 1, 1970 */
               long    tv_usec;    /* and microseconds */
          };

          struct timezone {
               int     tz_minuteswest; /* Greenwich */
               int     tz_dsttime;     /* type of dst correct to apply */
          };

2) To do a synchronous write to DISK, the fsync (2) system call should be
  used after the write(2) or writev (2) system call.  The fsync (2) system
  call causes all in-core copies of buffers for the associated file to be
  written to a DISK.  See fsync (2) manual page for more information.

Note that the use of the O_NDELAY and O_NONBLOCK flags in the open() system
call for controlling I/O applies only to FIFOs and communication lines like
tty's.  See open (2) manual pages for more information.
```

TA45078_Macintosh_and_CDI_Development__(TIL06576).pdf

Macintosh and CD-I Development (11/94)

I am interested in using the Macintosh to develop CD-I (compact disc interactive) applications. What can and cannot be done in this field?

* Is there a CD-I compatible player for the Macintosh?

* How would one develop an animation on the Macintosh and then transfer it to CD-I?

* Can sounds be created and manipulated on the Macintosh and then used on the CD-I?

This article has been archived and is no longer updated by Apple.

Currently, Macintosh is being used as a front-end device for assembling certain elements of CD-I. This is about the extent of what can be done with the Macintosh. Since the CD-I system is an alternative computer system to the Macintosh, we cannot duplicate a CD-I system exactly without accommodating the OS9 operating system.

The video portion of CD-I is compressed from analog video sources. Thus, preparing Macintosh animations for this format is the same as preparing animations for videotape. Using a program like MacroMind Director and an NTSC output video NuBus card, and recording the output onto videotape, would be the simplest way to provide video.

The quality of the compressed video coming from the CD-I compression methods is low compared to VHS tape. Generally, the playback of the video is around 12 frames per second for one quarter screen. The proposal provides for only 30,000 colors in the video image--far short of the Macintosh 24-bit capability.

Because CD-I uses digital audio, digital audio products from companies like Digidesign and New England Digital can be used for mastering the audio portion of the CD-I system. However, this master audio would then need to be sent through the CD-I compression method.

ADB: Detection of TTL Signals for Network Shutdown

I'm looking for an ADB device that lets me monitor at least three TTL signals and control one TTL signal. I want to implement a Macintosh program that will handle a number of uninterruptible power supplies (UPSs). The intention is that the program can shut down a Macintosh network gracefully.

Using an ADB device will free a serial port from being dedicated to monitoring a few lines for a change of state. Is there a device able to handle the above TTL signals?

This article has been archived and is no longer updated by Apple.
We have not been able to find an ADB-based product that has these abilities. The Apple Desktop Bus is typically used for products such as keyboards, trackballs, mice, and so on, and it isn't likely that someone has worked on something of this nature.

TA45081_Pascal_Clearing_the_video_screen_(TIL00658).pdf

Pascal: Clearing the video screen

This article has been archived and is no longer updated by Apple.
As described by Kenneth Bowles in Problem Solving Using Pascal, the routine CLEARSCREEN is a system function of the UCSD computer facility. By issuing a form feed to the standard Apple screen, the system intrinsic PAGE(OUTPUT) can perform a similar function on your system.

You can use the following procedure to clear the screen.

```
PROCEDURE CLEARSCREEN;
BEGIN
WRITE (CHR(12));
END;
```

As in the SETUP program, the procedure uses the character CHR(12) to clear the standard Apple video screen. Other external terminals may require a different value; for these terminals, modify the procedure by replacing CHR(12) with the appropriate control character (or characters) for "Erase Screen".

Macintosh Portable: Charging from 12-Volt Battery

Can the Macintosh Portable be charged from a 12-volt battery?

This article has been archived and is no longer updated by Apple.

Yes. One product that makes this possible is the Automobile Power Adapter from Lind Electronic Design. As we understand it, with the Adaptor, you can operate a Macintosh Portable while charging its battery from the 12-volt DC battery in an automobile, van, or boat. The adapter unit contains a voltage regulator and current-limit circuits that ensure safe computer operation and battery charging from a mobile power source. Lind includes cords for an automobile cigarette lighter and for the computer's power adapter jack with the adapter.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

AppleShare PC and LaserWriter Drivers

I installed AppleShare PC 2.01 on a PC on a mixed LocalTalk network. The Macintoshes in the workgroup use LaserWriter drivers version 6.0.1. It seems that AppleShare PC is not compatible with these drivers, and we get LaserWriter wars. Is there a fix or workaround?

This article has been archived and is no longer updated by Apple.
While the Macintosh LaserWriter drivers require a PostScript dictionary to be present in the LaserWriter, AppleShare PC does not. Printing from AppleShare PC to a LaserWriter connected as a PostScript device doesn't download anything other than the file being printed.

It does download an Epson emulation dictionary for each Epson job, but this persists only for the length of that job. It does not require or replace md (The Macintosh Laser Prep dictionary), and, therefore, won't cause any LaserWriter wars.

Theoretically, PC application that prints PostScript can wipe out md, or download its own dictionary that conflicts with 6.0.1. This is entirely dependent on the applications being used and could be tested by printing from each in turn until a conflict occurs.

We would first confirm that all of the Macintosh computers have LaserWriter and Laser Prep 6.0.1 installed. If so, check to see if one of the PC applications is causing the problem.

A/UX: AppleTalk "lpr" Problem (9/94)

At the UNIX prompt, I type: lpr /etc/hosts

The file does not print, and I repeatedly get the following messages on the console:

/usr/spool/lpd/AppleTalk/ofilter: pipe: cannot open
/usr/spool/lpd/AppleTalk/ofilter: pipe: cannot create

I guess I should add that the lpr command uses the default entry in /etc/printcap file. In the unmodified version (as distributed) it is the AppleTalk entry, which should print on whatever printer is currently selected by the Chooser.

This article has been archived and is no longer updated by Apple.
To let the AppleTalk printing service run correctly under the A/UX BSD printer spooler (/usr/lib/lpd, lpr, ...), the following files under each printer directory (for example /usr/spool/lpd/AppleTalk) should be owned by user "daemon" and group "daemon":

drwxrwxr-x 2 daemon daemon .
drwxrwxr-x 7 daemon daemon ..
-rwxr-xr-x 3 daemon daemon ifilter
-rwxr-xr-x 3 daemon daemon ofilter
-rwxr-xr-x 3 daemon daemon nfilter
prw-rw---- 1 daemon daemon pipe

The error message "...: pipe: cannot open" most likely indicates that the ownership or groupship of any of the above files might have been incorrectly set. Check yours, correct them, then restart the "lpr" command.

Because "lp" is the default printer in the BSD printer spooler system, the "lp|at|AppleTalk" entry in /etc/printcap is chosen by the printer daemon (/usr/lib/lpd). /usr/lib/lpd then passes all input file(s) to be printed to a remote PAP (Printer Access Protocol) server for printing. This is done by the input/output filter programs (ifilter, ofilter) provided under individual printer directory (/usr/spool/lpd/AppleTalk), which is in turn invoked by the "atprint" program which directly copies data to a remote PAP server.

Under "lpr", the destination PAP server is chosen as follows:

If the -Pprinter option of "lpr" command or the environment variable PRINTER is used or set, then the output goes to a specific printer. Otherwise, the system-wide default printer, the "lp" entry in /etc/printcap, is chosen, which is also the AppleTalk printer. The default AppleTalk printer is then chosen via the Chooser, from the Control Panel, or through the at_cho_prn utility.

We assume that you have correctly configured and set the AppleTalk in A/UX kernel.

A/UX 2.0.1: General Information

A/UX 2.0.1: General Information

This article has been archived and is no longer updated by Apple.

```
A/UX 2.0.1 is an incremental upgrade release to A/UX 2.0. It was
produced primarily to add support for the Macintosh IIsi.
A/UX 2.0.1 runs on all Macintosh models that support A/UX. There is no
CD version of the upgrade, however there is a CD available that contains
the full A/UX 2.0.1 release

Benefits and Features
---------------------
* Supports the Macintosh IIsi (with FPU installed)
* Supports multiple monitors on one Macintosh via the "Monitors" CDEV
* Supports adjustable mouse tracking via the "Mouse" CDEV
* Includes MacX 1.1
* Includes new version of the awk programming language
* Includes new version of the Korn shell, ksh-88
* Supports Macintosh System Software 6.0.7
* Is IEEE standard POSIX 1003.1-1990-compliant
* Includes version 5.65 of sendmail
* Includes changes to the A/UX header files, which provide function prototypes
 and ANSI symbol definitions for third-party ANSI C compilers
* Has asynchronous serial support
* Supports the use of function keys in CommandShell
* Mounts Macintosh HFS CD-ROM volumes to the desktop while logged in

CD-ROM Note
-----------
To properly operate an AppleCD SC, the Apple CD-ROM INIT must be installed in
the System Folder of the Macintosh startup volume, and the AppleCD SC must be
powered on at startup.
```

Macintosh Classic: Disk Errors May Be WDEF Virus

We have seen some strange error messages when inserting 800K diskettes, which have been formatted in a Macintos ah SE or Macintosh Plus, into a Macintosh Classic. When the disk icon appears on the desktop, and the user double-clicks on it, errors like "this is not a Macintosh Disk", "Error reading this diskette", and "Address error" appear.
This article has been archived and is no longer updated by Apple.
We have had reports of a variety of problems when users double-click on icons. The only situation that has been reproducible was traced back to the WDEF virus. Apparently, the WDEF virus causes this problem with System 6.0.7. (In earlier version of the system software, WDEF could be in the system, yet not create any major problems.)

Our suggestion is to use Disinfectant 3.7.1 or higher, or any of the other virus protection programs on the market, to check the Macintosh Classic for WDEF and eliminate the virus.

For information on downloading the latest version of Disinfectant refer to:
TIL aritcle 30487: "**Disinfectant: Macintosh Anti-Viral Utility**".

The Tech Info Library article#17159: "**Locating Vendor Information**", can help you search for a particular vendor's address and phone number.

Apple Pascal 1.3: Startup Slot

What is the memory location for the slot number of the drive that Apple Pascal starts up from? How can I change that information or location so the computer will think it was booted from the RAM disk (to which I've already copied the appropriate system files)?
This article has been archived and is no longer updated by Apple.
The internals of Apple II Pascal are proprietary and confidential and we cannot divulge such information.

However, it is possible to completely load Apple II Pascal into an Apple II RAM Expansion card and start up from it. Here's how:

1) Once you have started Apple Pascal and you are at the command line, type F(ile.

2) At the second command line, type V(ols. Write down the volume number with 2048 blocks. This is your RAM Expansion Card volume number.

3) Format the RAM Expansion Card. Type Q(uit and then X(ecute. This will prompt you for a file name. Type "Formatter" and press Return. Formatter will ask you for a volume to format: type the volume number you wrote down in step 2, and press Return.

4) Do a wild card copy of all the files on Volume 4 to the volume number of your RAM Expansion Card. Type F(ile then T(rans. When you're asked "Transfer What File?", type "#4:=" and press Return. At the "to where?" prompt, type your RAM Expansion Card volume number followed by ":=" and press Return.

5) When the copying is finished, make your RAM Expansion Card the startup volume. Type Q(uit followed by another Q and Y. Finally, type Control-Reset.

6) At the Applesoft BASIC prompt, type "PR#" followed by the slot number of your RAM Expansion Card. Pascal should start up.

Apple Pascal supports a maximum of 128K RAM for system memory use, and the remaining RAM may be used as a RAM disk only.

Macintosh IIsi/IIci/LC Built-in Video: No NTSC Output (11/94)

Can I display the Macintosh LC's output on an NTSC monitor? I looked into RGB-to-NTSC converters and found that the RasterOps Video Expander only works off a NuBus display card. My guess is that ComputerVideo's Video NTSC Encoder works the same way.

I know you can make a cable to pull black and white NTSC off Macintosh display cards. Given that, is there a way to pull NTSC off the built-in video on a Macintosh?

This article has been archived and is no longer updated by Apple.
While you can generate an RS-170 signal by shorting together pins on Apple's NuBus video cards, an NTSC compatible (not NTSC standard) signal cannot be generated by the built-in video ports of the Macintosh IIci, Macintosh IIsi, or Macintosh LC.

Lapis Technology produced a video adapter to allow the Macintosh LC to generate NTSC compatible video. Contact them for further information on pricing and availablility.

TA45095_Pascal_Interface_cards_in_peripheral_slot__(TIL00660).pdf

Pascal: Interface cards in peripheral slot #3

This article has been archived and is no longer updated by Apple.
The Pascal system will not appear to boot correctly on the standard Apple video if slot #3 has a Communications card, Serial card, or DC Hayes Micromodem card in it. Pascal reserves slot #3 for an external terminal, so when Pascal recognizes a card in this slot, it attempts to communicate with the assumed terminal and not with the default CONSOLE and SYSTERM (video and keyboard). Other cards may also cause this effect, which can be easily remedied by removing the card from slot #3.

TA45097_ProDOS_Filer_Changes_from__(TIL00661).pdf

ProDOS Filer 1.1: Changes from 1.0

These are the changes between Filer 1.0.1 and Filer 1.1.
This article has been archived and is no longer updated by Apple.
1) The critical speed tolerance of the formating routine was extended.

2) The format routine was made to allow for different size volumes in the same slot. The routine now correctly uses the UNIT number in the Device List in the Global Page as a pointer into the Driver Address table. Previously, the routine would only look at Drive 1 for the information on the size of the volume and would later write out an incorrect Bit Map and Directory after the formatting of the different device in drive 2.

3) The volume number is now transferred from source disk to destination disk in Volume Copy. The volume number on a format is now 1.

4) The 'DEVICE NOT FOUND' bug when trying to format previously unformated media was fixed.

The Formatter in ProDOS 1.0/Filer 1.0 would not format a disk in drive 2 if it had never been formatted. This problem also occurred in DuoDisks. The solution was to format the disk in DOS 3.3 and then re-format the disk with the Filer. We later released a new version of ProDOS 1.1.1 and the Filer 1.1.

5) The standard MLI QUIT call will now be executed when a selector is present.

6) Formating volumes consecutively will now start with a random 'nn' value ('/BLANKnn') in the default volume name and then continue increasing sequentially.

In addition, these are the changes made from Filer 1.0 to Filer 1.0.1

1) Interrupts were disabled during formating.

2) The BitMap create routines were corrected for all disk sizes.

Hard Disk 20SC: Connecting a terminator

This article has been archived and is no longer updated by Apple.

The actual Small Computer Systems Interface specification from ANSI states that each END of the daisy chained cables are terminated. This indicates that the HD20SC manual is 'incorrect' and the Apple SCSI Cabling System manual is correct.

The diagram on page 15 of the "Hard Disk 20SC Owner's Guide" shows the terminator on the extra SCSI port. On page 5 of the HD20SC manual, it shows that when connecting a single HD20S to a CPU, the SCSI System cable should connect the 2 machines, while the SCSI Terminator connects to the other port on the hard drive.

The top diagram on page 12 of "The Apple SCSI Cable System" shows the terminator goes between the cable and the (one) peripheral device. Page 10 of the SCSI Cable System manual states that for the same configuration that the System cable should connect directly to the SCSI Terminator and the other end of the Terminator connects to the SCSI device (in this case HD20SC).

In truth, both ways work. However, if you were to check the amount of line noise on both one-device setups, you might find a bit more noise on the incorrectly placed terminator configuration.

The terminator should be placed on the SCSI input of the first device. If the configuration has more than one device or more than 10 feet of SCSI cable hooked together, a second terminator should be placed on the pass through of the last device. If the user has a self-terminated SCSI device, it should be the last device on the chain. You may refer to the Apple SCSI Cabling System manual for all of the correct configurations.

VMS ENQLM: Quota Requirement for DAL/VAX/Rdb

I have problems while trying to use DAL with VAX/Rdb. I'm using DAL 1.2 (from DEC LanWORKS for Macintosh) with VAX/Rdb 3.1 under VMS 5.3. My connection (and associated processes) were killed when I try to use the IDAL utility with an account different than SYSTEM (or a copy of it). Some commands worked, (like DESCRIBE DATABASES) and some others (like SELECT) ended up with the connection terminated. I experimented and found that the solution was to set the ENQLM parameter for the user to a minimum value of 250.

I did not find any information about this in my documentation, and I know it's not a VAX/Rdb problem, because I can use VAX/Rdb SQL$ utility with the same ENQLM value without any problem. I have been able to reproduce the same problem on two CPUs, one MicroVAX 2000, and one 3300.
This article has been archived and is no longer updated by Apple.
As you might already know, on VMS, the Enqueue Quota (ENQLM) limits the number of locks a process (and its subprocesses) can own. VAX/Rdb uses RMS, which in turn uses the Lock Management Facility, to synchronize shared file access. One lock is used for every shared file, local buffer, global buffer section, and outstanding record lock. Users doing large amounts of file sharing should set the ENQLM to a large value. Typically, this number is recommended at 200. The DEFAULT account ENQLM is set at 100, so all accounts begin with a limit of 100 unless explicitly changed.

It is understandable why you need to increase ENQLM when selecting a large number of records from a database. Commands like DESCRIBE DATABASE do not require many locks and, therefore, worked with the low ENQLM. We don't know why Rdb SQL$ utility worked except for the speculation that IDAL might add the extra locking.

DAL support engineering told us that although they do not specify account quota requirements, in the documentation, they recommend changing user accounts quota to the VAX/Rdb requirements. The following are from VAX Rdb/VMS Installation Manual:

BYTLM (Byte Limit): at least 18,000 bytes
FILLM (Open File Quota): around 50 is an acceptable value
ENQLM (Enqueue Limit): at least 600 locks

The account should also have TMPMBX privilege.

Mac IIci: EtherTalk & Apple Internet Router Problem (11/94)

Macintosh IIci systems running the AppleTalk Internet Router and EtherTalk have been found to "freeze up" in certain high-traffic situations. What can I do?

This article has been archived and is no longer updated by Apple.
The solution is to install EtherTalk on the Mainctosh IIci using the Network Products Installer that was released with System 6.0.7. This installs a new version of the .ENET driver in the System file that resolves the problem.

Cache Cards for Macintosh IIci

Article Change History

02/09/93 - UPDATED
* Micron Technology acquired by Xceed Technologies
07/10/92 - REVIEWED
* For accuracy.

I need a cache card that plugs into the cache connector of the Macintosh IIci. What products are available besides the DayStar Fast Cache IIci?

This article has been archived and is no longer updated by Apple.

The only cache card for the Macintosh IIci that we know of, other than the Apple and DayStar cards, is the Micron Technology (acquired by Xceed Technologies) MBXC1. This card contains 128K of cache memory.

NOTE: As of September 1991, the Apple Macintosh IIci Cache Card is included with all Macintosh IIci computers.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

A/UX: "cpio" Does Not Support Symbolic Link Backups (8/94)

I have a question about cpio. I'm trying to back up the Macintosh System Folder under A/UX and the following command will back up only the unique files in the folder. The main problem is that an symbolic links in that folder do not get backed up.

Here is the command I'm using from the Command Shell:

```
cd /mac/sys/"System Folder"
ls -a | cpio -ovF > /dev/rfloppy0
```

This command installs the unique files on two successive floppies, but ignores the others. How can I get these files to be recognized by the cpio command?

This article has been archived and is no longer updated by Apple.
Symbolic links are analogous to aliases in the Macintosh OS. Neither the "cpio" nor "tar" commands under A/UX back up symbolic links. Rather, they copy only the symbolic names, not the actual data files.

In this case, you also need to copy the directories (/mac/lib/SystemFiles, for example) that contain the actual data files.

TA45103_MacX_and_X_Window_System_for_AUX_Are_ICCCM_Compliant__(TIL06626).pdf

MacX and X Window System for A/UX Are ICCCM Compliant (9/94)

Is the MacX v1.0 server and X Windows for A/UX ICCCM compliant?

This article has been archived and is no longer updated by Apple.
ICCCM stands for "Inter-Client Communication Conventions Manual." Yes, MacX and X Window for A/UX are both ICCCM compliant. Most of X11R3 and later client applications and Window Managers are designed to meet the ICCCM conventions. The ICCCM really has nothing to do with the X server; the convention is to make sure that all applications running X cooperate properly with the Window Manager and share the system resources politely.

Although MacX is a server, it has a built-in Window Manager, the functionality of which is designed to conform to the ICCCM conventions.

Macintosh IIsi: Use Excel 2.2a or Later

The Macintosh IIsi bombs when trying to use Excel 2.2. Does System 6.07 fix the problem? Is there a way to trick the Macintosh IIsi so that it doesn't assume it has a math coprocessor and lets you run Excel?

This article has been archived and is no longer updated by Apple.
There are known problems with Excel versions prior to 2.2a running on the Macintosh IIsi. Microsoft knows of the problem and suggests that affected customers upgrade to 2.2a or higher.

System 6.0.7 does not fix the problem with Excel, but is required for the Macintosh IIsi anyway. Be sure that you are using System 6.0.7 before troubleshooting further.

There is a way to make older versions of Excel ignore the FPU, or in the case of the Macintosh IIsi, not look for what isn't there. Hold down the Command, Shift, and Option keys at launch time (when double-clicking the Excel icon).

DAL Access: Not Supported by Teradata Database

I have a Teradata Database Server (Model 1012) attached to an IBM Host Environment running VM/CMS.

I've been involved in a few VAX VMS DAL installations, but never one on the IBM side. What pieces are needed for the Macintoshes to be able to access the Teradata DBMS through the IBM Host?

My guess is:

* A Macintosh Client DAL Application or DA (ClearAccess, WingZ, HyperCard, and so on).

* On the Host, DAL for VM/CMS.

* A product called EQT.

* 3270 support on the workstation (IRMA, Avatar, Tri-Data, and so on).

* Correct 3270 API to support the hardware used.

That's where I am confused. EQT lets you do SQL queries through DAL on an IBM Host. Because Teradata is not one of the "supported" databases (Ingres, Informix, Sybase, and so on), it requires its own adapter. Is this correct?

If I go with the EQT Product, do I even need DAL on the Host? If EQT supports DAL, can I use products like WingZ to access?
This article has been archived and is no longer updated by Apple.
Before we answer your questions, let's look at what EQT does:

EQT (Executive Query Tool) is a Query Tool developed by Red Brick Systems. It provides point-and-click access to relational databases, regardless of workstation platform, the database server, or the server hardware. It runs on Macintosh and DOS Windows. Future releases will run on OS/2 Presentation Manager, and on UNIX workstations. It can retrieve data from Teradata, Oracle, Ingres, Sybase, DB2, Informix, and Rdb databases.

EQT for CL/1 is an old name for an announced product called Claris Query Tool which uses three mechanism to access databases: Data Access Language (DAL from Network Innovations), DB Library (Sybase), and SQL-Net (Oracle). Claris Query Tool will be shipped in 1991 but will not be able to access Teradata database machines. For more information about Claris Query Tool, contact Claris.

Red Brick Systems retains the right to market and support EQT for the Teradata Systems. For more information, contact Red Brick.

Claris Query Tool uses DAL as one of its mechanism to access databases. You have to use the EQT version from Red Brick Systems to access the Teradata databases. Red Brick uses Teradata's access mechanism.

EQT is a Query Tool to access databases. To our knowledge, you cannot use WingZ to access the Teradata database directly, because Teradata does not support the DAL access. You can, however, access the database using Red Brick's EQT and import the data (cut and paste) into the spreadsheet.

As of release 1.3 DAL supported access to Teradata's DBC/1012 DBMS but only under an MVS operating system.

Worldwide Network: Missing Servers Issue

I have questions regarding the performance of a worldwide Liaison network. Servers are dropping off the network, and it seems to be a result of the network configuration.

I need to know what happens when I do a read of a file on an AppleShare server in a remote location over a slow link. In brief, I have a program in Toronto, London, Madrid, Zurich, Frankfurt, and Paris that reads a file from an AppleShare server in New York.

Sometimes the link (Liaison over an asynchronous line into the Tymnet packet Switched network) "breaks" and other times, we seem to "lose" the server. When we try to reconnect to the server, the branch locations sometimes do not "see" the server in the Chooser window for a long enough period to select the server physically. We cannot, therefore, restart the application. Their observation has been 15 seconds of availability. This does not always happen, but it happens too often to not lodge a complaint.

The application checks on and reports all sorts of errors on a read, and it does know when it cannot open a file, because a server is unavailable. I am doing PBHOpenDeny opens and PBRead calls. We have asked the Tymnetnetwork people to look into this, and they have asked the following questions:

1) When you open the Chooser window and select a zone, how do the lists of servers appear?

- How long does it take to get the list up?

- Why do some servers come into and disappear from the list?

- Why do some servers never appear in the Chooser window? Is this because the servers' response time is very slow, and, therefore, the response is ignored until the next request is broadcast? If so, how long is this window? (What is the maximum round-trip delay from the branch Macintosh to the AppleShare server and back?)

2) On a read, when a read request is sent to the remote AppleShare file server (from branch to New York) what is the timeout period before the packet is determined to be lost, and is thus retransmitted?

3) On a normal AppleShare read, if a data packet times out, how many retries are made before AppleShare decides that the link to the server is dead? Or, how long does AppleShare continue trying before it gives up?

4) If I do a read, should I always get back a response, or is it possible that if the Macintosh has lost the file server, AppleShare will be unable to respond, and that the reading application will appear to hang? This seems to happen sometimes, from what the branch people say. Sometimes, if we lose the link to New York, the whole Macintosh hangs and must be restarted.

This article has been archived and is no longer updated by Apple.
What version of Liaison are you using? Versions before 3.0 are no longer supported. Farallon purchased the product from InfoSphere and is offering support only for version 3.0 and later (3.0.5 is compatible with System 7.1), which fixed several bugs and added support for AppleTalk phase 2.

One issue in versions before 3.0 was the inability of Liaison to display zone lists when the zone list transverses more than one ZIP packet (around 40 zones depending on the size of the name). You should call Farallon to discuss the current issues the account is experiencing with the product. We cannot control how third-parties choose to implement routers and other such products based around AppleTalk. This can cause issues if the product was implemented in a way that the protocols were never designed to accommodate.

Because the AppleTalk protocols were never designed to work over slow asynchronous links or over wide-area networks, there are several issues that need to be addressed before AppleTalk can become a valid protocol for use in these types of environments.

Here are direct answers to your questions:

1) This is how it really works in a nutshell:

The Chooser sends out a Name Binding Protocol (NBP) packet looking for all devices of type XXXXXX, for example, type LaserWriter. It sets up a buffer of 512 bytes for the responses. The responses look like:

```
device name length          1 byte
  device name                 variable bytes      e.g. MyLaser-Hands off
  type name length            1 byte
  type name                   variable bytes      e.g. LaserWriter
  zone field length           1 byte
  zone name field             variable bytes      probably *
```

The Chooser gets a packet back for each device, i.e., each LaserWriter. When the 512-byte buffer is full of these packets, it stops looking for device names to display. This means that some LaserWriters might not be displayed immediately. If you leave the Chooser window open, however, the Chooser will continue to send out NBP lookups every 1.47 seconds.

Different LaserWriters could respond more quickly each time. In this case, you may see the Chooser show and hide various devices.

You can see from this that the number of devices Chooser can show depends on how long the type name is (like "LaserWriter") and how long the device names are. The number 18 is an average number, based on the device type being about 13 or 14 characters long and the device name being about 10 or 11 characters long. In System 7.0, the buffer size the Chooser will use will be increased to 1024. This means, on average, the Chooser can display about 36 devices.

2) This depends on the direction of the transfer. Workstation to Server copy takes 6 seconds and server to Workstation copy about 2 seconds.

3) Retries are set to infinite. The session timer for the connection is set to 2 minutes. This is really what dictates how long the reads are attempted before the transaction is aborted. The session timer is restarted each time a tickle packet is received by either the workstation or the server. Tickle packets are sent out every 60 seconds by both the server and the workstation to allow a way of detecting if the other end of the connection has gone down.

4) No, you aren't guaranteed a response, but the session timer should expire after 2 minutes and pop up a dialog telling you that the server has unexpectedly quit.

Apple IIGS: Not Enough Disk space for 5.25 Desktop Disk

This article has been archived and is no longer updated by Apple.

There is no way to create a ProDOS 8 or ProDOS16 Desktop disk on a 5.25 floppy: there is just not enough disk space. However, a startup P8 (ProDOS 8) disk can be created. As an example, below are instructions of how to create a startup ProDOS 8 System Utilities disk.

1. Format a 5.25 disk

2. Copy these 5 files from System Utilities to the 5.25 disk:

a. P8 (ProDOS 1.2, found in the SYSTEM sub-directory)
b. SYSUTIL.SYSTEM *
c. GSSU0 *
d. GSSU1 *
e. GSSUE1 *

* These 4 files comprise the System Utilities program and can be found in the SYS.UTILS sub-directory. They must be kept in the same directory.

3. Rename the file 'P8' to 'PRODOS'

System Utilities may now be booted from the floppy disk. The files take up around 180 blocks and leave about 100 blocks for extra file storage.

LaserWriter Driver 6.0.2: Resource for Printing Envelopes

What are the advantages of LaserWriter driver 6.0.2 over LaserWriter driver 6.0.1?

This article has been archived and is no longer updated by Apple.
LaserWriter driver 6.0.2 is included with System Software 6.0.7, in the Apple Color folder on the Printing Tools disk. The only difference between LaserWriter driver 6.0.1 and LaserWriter driver 6.0.2 is that LaserWriter driver 6.0.2 has an added resource for printing envelopes.

In Page Setup, you now have the options of either printing envelopes from the edge or from the center. This was done for the Personal LaserWriter.

Manual feed on a LaserWriter II has two paper guides which move in and out together, allowing you to print from the center. Manual feed on the Personal LaserWriter has only one paper guide, which moves from the edge out. You would, therefore, want to put the envelope all the way over to the edge. LaserWriter driver 6.0.2 gives you the option to do this.

TA45109_AppleShare_PC_No_Support_For_Digitals_DEC_Network_Card_LC_(TIL06631).pd

AppleShare PC: No Support For Digital‘s DEC Network Card LC

Does Apple support Digital's DEC Etherworks LC card for the PC with AppleShare PC 2.0?

This article has been archived and is no longer updated by Apple.
AppleShare PC can work with any network card that has an ODI (Open Data-Link Interface) compliant MLID. However, the only MLIDs we know of are those supplied with AppleShare PC. We haven't heard of anyone writing one for a DEC Ethernet card, although it could be done.

If you know of someone interested in developing an MLID for a specific card, information is available from APDA in the form of the Open Data-Link Interface Developer's Guide, part number M0355LL/A. This document details the specification, and provides example source code for a working driver. For more details, search the Technical Info library under "APDA."

How to Remove AppleShare PC Code from PC Memory

I am running AppleShare PC (2.01). Currently, WordPerfect runs on the PC (with 512K RAM) until I start AppleShare using ABOTH. After checking E-mail, which is the main reason I use AppleShare PC, I type AOFF to kill AppleShare, but WordPerfect no longer has enough room to fully execute. Only a warm reboot with Control-Alt-Del frees up the memory. Is there any way (short of rebooting) I can free ALL memory after typing AOFF?

This article has been archived and is no longer updated by Apple.

There is a way to remove all AppleShare PC code without rebooting. It requires the use of mark/release utilities. This kind of program is used to mark a position in memory so that TSR programs and drivers loaded later, like AppleShare PC, can be removed with the companion release program.

Macintosh: Viewing CCITT Group IV Images

I understand that one or more vendors have products that let CCITT Group IV images be decompressed and viewed (pan, zoom, scan, and so on) on the Macintosh. What are the supporting products and companies?

The images we have are large 2-bit images of engineering drawings. They conform to the DOD CALS raster Specification, which is essentially 200 DPI CCITT G4.

This article has been archived and is no longer updated by Apple.
We found the following information concerning Creative Solutions' Compression, Expression and Rotation Board.

"A NuBus board that provides compression, expansion and rotation on image data.

"The Compression/Expansion/Rotation board performs all of the above functions on image data. The board features: compression or expansion throughput in excess of 16 million pixel elements per second; ROM with standard half duplex Macintosh device drivers that are installed automatically at startup; CCITT input driver reads data to a supplied buffer and returns the actual count read; conversion modes set via control calls to either input or output drivers; and accelerated hardware rotation of 32 by 32 pixel tiles."

For more vendor information, search under "Creative Solutions."

Macintosh IIsi: NuBus Card Power Draw

Apple data sheets state that the Macintosh IIsi NuBus cards should not draw more than 13.3 watts of power. I'm interested in putting some Macintosh IIsi computers into a Token Ring environment where the TokenTalk NB Card draws 15 watts. Has this combination been tested, and if so what was the result?

This article has been archived and is no longer updated by Apple.

Because of the low-power design of many Macintosh IIsi components, the computer should be able to handle cards requiring up to 20 watts. Although this exceeds the normal, single-slot, NuBus specification, there is adequate power available in Apple supplied configurations. However, if you use third-party internal hard drives or other components that draw additional power, the power available to the NuBus card may be lower.

All Macintosh IIsi configurations we ship can handle the 15-Watt requirement of a TokenTalk NB Card. It has been tested, and is fully supported with the Macintosh IIsi.

ANSI S1.29-1979: Bystander Position Definition

The American National Standard document ANSI S1.29-1979 defines bystander position:
This article has been archived and is no longer updated by Apple.
For equipment which does not require attention while in the operating mode, an operator position need not be defined. One or more bystander positions shall be selected and defined in the test plan or equipment specifications. The bystander position shall be 1.00 m away from the projection of the reference parallelepiped on the horizontal plane and 1.50 m above the floor.
